LIMITING SPECTRAL DISTRIBUTION OF CIRCULANT TYPE MATRICES
WITH DEPENDENT INPUTS

Abstract

Limiting spectral distribution (LSD) of scaled eigenvalues of circulant, symmetric circulant and a class of k-circulant matrices are known when the input sequence is independent and identically distributed with finite moments of suitable order. We derive the limiting spectral distribution of these matrices when the input sequence is a stationary, two sided moving average process of infinite order. The limits are suitable mixtures of normal, symmetric square root of the chisquare, and other mixture distributions, with the spectral density of the process being involved in the mixtures.

Keywords Large dimensional random matrix, eigenvalues, circulant matrix, symmetric circulant matrix, reverse circulant matrix, k circulant matrix, empirical spectral distribution, limiting spectral distribution, moving average process, spectral density, normal approximation.

1 Introduction

Suppose $\lambda_1, \lambda_2, \ldots, \lambda_k$ are all the eigenvalues of a square matrix $A$ of order $k$. Then the empirical spectral distribution (ESD) of $A$ is defined as

$$F_A(x, y) = k^{-1} \sum_{i=1}^{k} \mathbb{I}\{R(\lambda_i) \leq x, \ I(\lambda_i) \leq y\},$$

where for any $z \in \mathbb{C}$, $R(z)$, $I(z)$ denote the real and imaginary part of $z$ respectively. Let $\{A_n\}_{n=1}^{\infty}$ be a sequence of square matrices (with growing dimension) with the corresponding ESD $\{F_{A_n}\}_{n=1}^{\infty}$. The Limiting Spectral Distribution (or measure) (LSD) of the sequence is defined as the weak limit of the sequence $\{F_{A_n}\}_{n=1}^{\infty}$, if it exists.

Suppose elements of $\{A_n\}$ are defined on some probability space $(\Omega, \mathcal{F}, \mathbb{P})$, that is $\{A_n\}$ are random. Then $\{F_{A_n}(\cdot)\}$ are random and are functions of $\omega \in \Omega$ but we suppress this dependence. Let $F$ be a nonrandom distribution function. We say the ESD of $A_n$ converges to $F$ in $L_2$ if at all continuity points $(x, y)$ of $F$,

$$\int_{\Omega} |F_{A_n}(x, y) - F(x, y)|^2 d\mathbb{P}(\omega) \to 0 \text{ as } n \to \infty. \quad (1.1)$$

If the eigenvalues are real then it is understood that $\{F_{A_n}\}$ and $F$ are functions of one variable. It may be noted that (1.1) holds if $\mathbb{E}[F_{A_n}(t)] \to F(t)$ and $\mathbb{V}[F_{A_n}(t)] \to 0$ at all continuity points $t$ of $F$. We often write $F_n$ for $F_{A_n}$ when the matrix under consideration is clear from the context.

For detailed information on existence and identification of LSD in different contexts, see Bai (1999) and also Bose and Sen (2008). There are many universality results available in this context. However, most of the existing work on LSD assumes the input sequence $\{x_i\}$ to be independent. It would be quite interesting to see what type of universality results continue to hold if dependent inputs are allowed. With the current methods used to establish LSD, such as the moment method or the Stieltjes transform method, it does not appear to be easy to extend the known results on LSD to general dependent situations for all types of matrices. There are only very few works dealing with dependent inputs. For instance, Bose and Sen (2008) establishes LSD for some specific type of dependent entries for a few matrices.

In this article we focus on the LSD of circulant type matrices— the circulant, the symmetric circulant, the reverse circulant and the so called $k$-circulant for suitable values of $k$. We assume specific type of dependent inputs, namely, we assume that $\{x_i\}$ is a stationary linear process. Stationary linear process is an important class of dependent sequence. For instance the widely used stationary time series models such as AR, MA, ARMA are all linear processes. Under very modest conditions on the process, we are able to establish LSD for these matrices. These LSD are functions of the spectral density of the process and hence are universal. Consider the following condition

**Assumption A** $\{x_i\}$ are independent, $\mathbb{E}(x_i) = 0$, $\mathbb{V}(x_i) = 1$ and $\sup_i \mathbb{E}|x_i|^3 < \infty$.

We first describe the different matrices that we deal with. These may be divided into four classes:

(i) The **circulant matrix** is given by
Sen (2006) shows that if Assumption \( A \) is satisfied then the ESD of \( C_n \) converges in \( L^2 \) to the two-dimensional normal distribution given by \( N_2(0, D) \) where \( D \) is a diagonal matrix with diagonal entries \( 1/2 \). Meckes (2009) shows similar type of result for independent complex entries. In particular, if \( \mathbb{E}(x_j) = 0, \mathbb{E}(x_j^2) = \alpha, \mathbb{E}|x_j|^2 = 1 \) for some \( \alpha \in \mathbb{C} \) and
\[
\lim_{n \to \infty} \frac{1}{n} \sum_{j=0}^{n-1} \mathbb{E}(|x_j|^2 1_{|x_j| > \epsilon \sqrt{n}}) = 0
\]
for every \( \epsilon > 0 \), then the ESD converges in \( L^2 \) to the standard complex normal distribution.

(ii) The symmetric circulant matrix is defined as
\[
SC_n = \frac{1}{\sqrt{n}} \begin{bmatrix}
x_0 & x_1 & x_2 & \ldots & x_{n-3} & x_{n-2} & x_{n-1} \\
x_{n-1} & x_0 & x_1 & \ldots & x_{n-4} & x_{n-3} & x_{n-2} \\
x_{n-2} & x_{n-1} & x_0 & \ldots & x_{n-5} & x_{n-4} & x_{n-3} \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\
x_1 & x_2 & x_3 & \ldots & x_{n-1} & x_0 & x_{n-1}
\end{bmatrix}_{n \times n}.
\]
Bose and Mitra (2002) show that if \( \{x_i\} \) satisfies Assumption \( A \), then the ESD of \( SC_n \) converges weakly in \( L^2 \) to the standard normal distribution.

The palindromic Toeplitz matrix is the palindromic version of the usual symmetric Toeplitz matrix. It is defined as (see Massey et.al. (2007)),
\[
PT_n = \frac{1}{\sqrt{n}} \begin{bmatrix}
x_0 & x_1 & x_2 & \ldots & x_{n-2} & x_{n-1} & x_0 \\
x_1 & x_0 & x_1 & \ldots & x_{n-3} & x_{n-2} & x_1 \\
x_2 & x_1 & x_0 & \ldots & x_{n-4} & x_{n-3} & x_2 \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\
x_1 & x_2 & x_3 & \ldots & x_0 & x_1 & x_0
\end{bmatrix}_{n \times n}.
\]
Its behavior is closely related to the symmetric circulant matrix. It may be noted that the \( n \times n \) principal minor of \( PT_{n+1} \) is \( SC_n \). Massey et.al. (2007) establish the Gaussian limit for \( F_{PT_n} \). Bose and Sen (2008) show that if the input sequence \( \{x_i\} \) is independent with mean zero and variance 1 and are either (i) uniformly bounded or (ii) identically distributed, then the LSD of \( PT_n \) is standard Gaussian. They also observe that if the LSD of any one of \( PT_n \) and \( SC_n \) exist, then the other also exists and they are equal.

(iii) The reverse circulant matrix is given by
\[
RC_n = \frac{1}{\sqrt{n}} \begin{bmatrix}
x_0 & x_1 & x_2 & \ldots & x_{n-2} & x_{n-1} \\
x_1 & x_2 & x_3 & \ldots & x_{n-1} & x_0 \\
x_2 & x_3 & x_4 & \ldots & x_0 & x_1 \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
x_{n-1} & x_0 & x_1 & \ldots & x_{n-3} & x_{n-2}
\end{bmatrix}_{n \times n}.
\]
Bose and Mitra (2002) show that if \( \{x_i\} \) satisfies Assumption A then the ESD of \( RC_n \) converges weakly in \( L_2 \) to \( F \), which is the symmetric square root of the chi-square with two degrees of freedom, having density
\[
f(x) = |x| \exp(-x^2), \quad -\infty < x < \infty.
\]
Equation 1.2

(iv) For positive integers \( k \) and \( n \), the \( n \times n \) \( k \)-\textit{circulant} matrix is defined as
\[
A_{k,n} = \begin{bmatrix}
x_0 & x_1 & x_2 & \cdots & x_{n-2} & x_{n-1} \\
x_{n-k} & x_{n-k+1} & x_{n-k+2} & \cdots & x_{n-2} & x_{n-1} \\
x_{n-2k} & x_{n-2k+1} & x_{n-2k+2} & \cdots & x_{2k} & x_{2k+1} \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
x_{-k} & x_0 & x_1 & \cdots & x_{n-2} & x_{n-1}
\end{bmatrix}_{n \times n}.
\]

We emphasize that all subscripts appearing in the entries above are calculated modulo \( n \). The first row of \( A_{k,n} \) is \( (x_0, x_1, x_2, \ldots, x_{n-1}) \) and for \( 1 \leq j < n - 1 \), its \((j+1)\)th row is obtained by giving its \( j \)-th row a right circular shift by \( k \) positions (equivalently, \( k \) mod \( n \) positions). Here we have dropped the \( \frac{1}{n} \) factor from the definition of the matrix so that subsequent formula for eigenvalues remains simple. Establishing the LSD for general \( k \)-\textit{circulant} matrices appears to be a difficult problem.

Bose, Mitra and Sen (2008) show that if \( \{x_i\} \) are i.i.d. \( N(0,1) \), \( k = n^{o(1)} \geq 2 \) and \( g\text{cd}(k,n) = 1 \) then the LSD of \( F_{n^{-1/2}A_{k,n}} \) is degenerate at zero, in probability. They also derive the following LSD. Suppose \( \{x_i\} \) are i.i.d. satisfying Assumption C, given below. Let \( \{E_i\} \) be i.i.d. \( \text{Exp}(1) \), \( U_1 \) be uniformly distributed over \((2g)\)-th roots of unity, \( U_2 \) be uniformly distributed over the unit circle where \( \{U_1\} \), \( \{E_i\} \) are mutually independent. Then as \( n \to \infty \), \( F_{n^{-1/2}A_{k,n}} \) converges weakly in probability to
\[
\begin{align*}
(i) \quad & U_1(\prod_{i=1}^g E_i)^{1/2g} \text{ if } k^g = -1 + sn, \ g \geq 1, \ s = o(n^{1/3}), \\
(ii) \quad & U_2(\prod_{i=1}^g E_i)^{1/2g} \text{ if } k^g = 1 + sn, \ g \geq 2 \text{ and } s = \begin{cases} o(n) & \text{if } g \text{ is even} \\
o(n^{g+1}) & \text{if } g \text{ is odd}
\end{cases}
\end{align*}
\]

We investigate the existence of LSD of the above matrices under the following situation.

\textbf{Assumption B} \( \{x_n; n \geq 0\} \) is a two sided moving average process
\[
x_n = \sum_{i=-\infty}^{\infty} a_i \epsilon_{n-i}, \quad \text{where} \quad a_n \in \mathbb{R} \quad \text{and} \quad \sum_{n \in \mathbb{Z}} |a_n| < \infty.
\]

\textbf{Assumption C} \( \{\epsilon_i\}, i \in \mathbb{Z} \) are i.i.d. random variables with mean zero, variance one and \( \sup_i \mathbb{E}|\epsilon_i|^{2+\delta} < \infty \) for some \( \delta > 0 \).

We show that the LSD of the above matrices continue to exist in this dependent situation under appropriate conditions on the spectral density of the process. The LSD turn out to be appropriate mixtures of, the normal distribution, the “symmetric” square root of the chi-square distribution, and, some other related distributions. Quite expectedly, the spectral density of the process is involved in these mixtures. Our results also reduce to the results quoted above for the i.i.d. situation.

In Section 2 we describe the nature of the eigenvalues of the above matrices and describe the spectral density and set up notation. In Section 3 we state the main results and report some simulation
which demonstrate our theoretical results. The main proofs are given in Section 4 and the proofs of some auxiliary Lemma are given in the Appendix.

Some of the results reported in this article have been reported in the unpublished technical reports Bose and Saha (2008a), Bose and Saha (2008b), Bose and Saha (2009).

2 Preliminaries

2.1 Spectral density and related facts

Under Assumptions B and C, $\gamma_h = Cov(x_{t+h}, x_t)$ is finite and $\sum_{j \in \mathbb{Z}} |\gamma_j| < \infty$. The spectral density function $f$ of $\{x_n\}$ exists, is continuous, and is given by

$$f(\omega) = \frac{1}{2\pi} \sum_{k \in \mathbb{Z}} \gamma_k \exp(ik\omega) = \frac{1}{2\pi} \left[ \gamma_0 + 2 \sum_{k \geq 1} \gamma_k \cos(k\omega) \right] \text{ for } \omega \in [0, 2\pi].$$

Let

$$I_n(\omega_k) = \frac{1}{n} \sum_{t=0}^{n-1} x_t e^{-it\omega_k}^2, \quad k = 0, 1, \ldots, n - 1,$$

(2.1)
denote the periodogram of $\{x_t\}$ where $\omega_k = 2\pi k/n$ are the Fourier frequencies. Let

$$C_0 = \{t \in [0, 1] : f(2\pi t) = 0\}.$$  

(2.2)

Define

$$a(e^{i\omega}) = \sum_{j=-\infty}^{\infty} a_j e^{ij\omega}, \quad a_1(e^{i\omega}) = R[a(e^{i\omega})], \quad a_2(e^{i\omega}) = I[a(e^{i\omega})].$$

(2.3)

It is easy to see that

$$|a(e^{i\omega})|^2 = |a_1(e^{i\omega})|^2 + |a_2(e^{i\omega})|^2 = 2\pi f(\omega).$$

Let

$$B(\omega) = \begin{pmatrix} a_1(e^{i\omega}) & -a_2(e^{i\omega}) \\ a_2(e^{i\omega}) & a_1(e^{i\omega}) \end{pmatrix} \quad \text{and for } g \geq 2,$$

$$B(\omega_1, \omega_2, \ldots, \omega_g) = \begin{pmatrix} a_1(e^{i\omega_1}) & -a_2(e^{i\omega_1}) & 0 & 0 & \cdots & 0 \\ a_2(e^{i\omega_1}) & a_1(e^{i\omega_1}) & 0 & 0 & \cdots & 0 \\ 0 & 0 & a_1(e^{i\omega_2}) & -a_2(e^{i\omega_2}) & \cdots & 0 \\ 0 & 0 & a_2(e^{i\omega_2}) & a_1(e^{i\omega_2}) & \cdots & 0 \\ 0 & 0 & 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & \cdots & a_1(e^{i\omega_g}) & -a_2(e^{i\omega_g}) \\ 0 & 0 & 0 & \cdots & a_2(e^{i\omega_g}) & a_1(e^{i\omega_g}) \end{pmatrix}.$$  

The above functions will play a crucial role in the statements and proofs of the main results later.

2.2 Description of eigenvalues

We now describe the eigenvalues of the four classes of matrices. Let $[x]$ be the largest integer less than or equal to $x$. 

5
(i) **Circulant Matrix.** Its eigenvalues \( \{ \lambda_i \} \) are (see for example Brockwell and Davis (2002)),

\[
\lambda_k = \frac{1}{\sqrt{n}} \sum_{l=0}^{n-1} x_l e^{i \omega_k l} = b_k + ic_k \quad \forall \, k = 1, 2, \ldots, n,
\]

where

\[
\omega_k = \frac{2 \pi k}{n}, \quad b_k = \frac{1}{\sqrt{n}} \sum_{l=0}^{n-1} x_l \cos(\omega_k l), \quad c_k = \frac{1}{\sqrt{n}} \sum_{l=0}^{n-1} x_l \sin(\omega_k l).
\]

(2.4)

(ii) **Symmetric Circulant Matrix.** The eigenvalues \( \{ \lambda_i \} \) of \( SC_n \) are given by:

(a) for \( n \) odd:

\[
\lambda_0 = \frac{1}{\sqrt{n}} [x_0 + 2 \sum_{j=1}^{[n/2]} x_j]
\]

\[
\lambda_k = \frac{1}{\sqrt{n}} [x_0 + 2 \sum_{j=1}^{[n/2]} x_j \cos \left( \frac{2 \pi k j}{n} \right)], \quad 1 \leq k \leq [n/2]
\]

(b) for \( n \) even:

\[
\lambda_0 = \frac{1}{\sqrt{n}} [x_0 + 2 \sum_{j=1}^{2^{n-1}/2} x_j + x_{n/2}]
\]

\[
\lambda_k = \frac{1}{\sqrt{n}} [x_0 + 2 \sum_{j=1}^{2^{n-1}/2} x_j \cos \left( \frac{2 \pi k j}{n} \right) + (-1)^k x_{n/2}], \quad 1 \leq k \leq n/2
\]

with \( \lambda_{n-k} = \lambda_k \) for \( 1 \leq k \leq [n/2] \) in both the cases.

(iii) **Palindromic Toeplitz matrix.** As far as we know, there is no formula solution for the eigenvalues of the palindromic Toeplitz matrix. As pointed out already, since the \( n \times n \) principal minor of \( PT \) is \( SC_n \), by interlacing inequality \( PT \) and \( SC_n \) have identical LSD.

(iv) **Reverse circulant matrix.** The eigenvalues are given in Bose and Mitra (2002):

\[
\begin{align*}
\lambda_0 &= -n^{-1/2} \sum_{t=0}^{n-1} x_t, \\
\lambda_{n/2} &= n^{-1/2} \sum_{t=0}^{n-1} (-1)^t x_t, \quad \text{if } n \text{ is even} \\
\lambda_k &= -\lambda_{n-k} = \sqrt{I_n(\omega_k)}, \quad 1 \leq k \leq \lfloor n/2 \rfloor.
\end{align*}
\]

(v) **k-Circulant Matrix.** The structure of its eigenvalues is available in Zhou (1996). A more detailed analysis and related properties of the eigenvalues, useful in the present context, have been developed in Section 2 of Bose, Mitra and Sen (2008). Let

\[
\nu = \nu_n := \cos(2 \pi /n) + i \sin(2 \pi /n), \quad i^2 = -1 \quad \text{and} \quad \lambda_k = \sum_{l=0}^{n-1} x_l \nu^l, \quad 0 \leq j < n.
\]

(2.5)

For any positive integers \( k, n \), let \( p_1 < p_2 < \ldots < p_c \) be all their common prime factors so that,

\[
n = n' \prod_{q=1}^{c} p_{\beta_q}^q \quad \text{and} \quad k = k' \prod_{q=1}^{c} p_{\alpha_q}^q.
\]
Here $\alpha_q, \beta_q \geq 1$ and $n', k', p_q$ are pairwise relatively prime. For any positive integer $s$, let $Z_s = \{0, 1, 2, \ldots, s - 1\}$. Define the following sets

$$S(x) = \{xk^b \text{ mod } n' : b \geq 0\}, \quad 0 \leq x < n'.$$

Let $g_x = |S(x)|$. Define

$$v_{k,n'} := |\{x \in \mathbb{Z}_{n'} : g_x < g_1\}|.$$ (2.6)

We observe the following about the sets $S(x)$.

1. $S(x) = \{xk^b \text{ mod } n' : 0 \leq b < |S(x)|\}$.
2. For $x \neq u$, either $S(x) = S(u)$ or $S(x) \cap S(u) = \phi$. As a consequence, the distinct sets from the collection $\{S(x) : 0 \leq x < n'\}$ forms a partition of $\mathbb{Z}_{n'}$.

We shall call $\{S(x)\}$ the eigenvalue partition of $\{0, 1, 2, \ldots, n-1\}$ and we will denote the partitioning sets and their sizes by

$$\{\mathcal{P}_0, \mathcal{P}_1, \ldots, \mathcal{P}_{l-1}\}, \quad n_i = |\mathcal{P}_i|, \quad 0 \leq i < l.$$ (2.7)

Define

$$y_j := \prod_{t \in \mathcal{P}_j} \lambda_{t y}, \quad j = 0, 1, \ldots, l - 1 \quad \text{where} \quad y = n/n'.$$

Then the characteristic polynomial of $A_{k,n}$ (whence its eigenvalues follow) is given by

$$\chi(A_{k,n}) = \lambda^{n-n'} \prod_{j=0}^{l-1} (\lambda^{n_j} - y_j).$$ (2.8)

### 3 Main results

For any Borel set $B$, $\lambda(B)$ will denote its Lebesgue measure in the appropriate dimension.

#### 3.1 Circulant Matrix

Define for $(x, y) \in \mathbb{R}^2$ and $\omega \in [0, 2\pi]$,

$$H_C(\omega, x, y) = \begin{cases} \mathbb{P}(B(\omega)(N_1, N_0) \leq \sqrt{2}(x, y)) & \text{if } f(\omega) \neq 0, \\ I(x \geq 0, y \geq 0) & \text{if } f(\omega) = 0. \end{cases}$$

**Lemma 1.** (i) For fixed $x, y$, $H_C$ is a bounded continuous function in $\omega$.

(ii) $F_C$ defined as follows is a proper distribution function.

$$F_C(x, y) = \int_0^1 H_C(2\pi s, x, y) ds.$$ (3.1)

(iii) If $\lambda(C_0) = 0$ then $F_C$ is continuous everywhere and can be expressed as

$$F_C(x, y) = \int \int \mathbb{I}_{(v_1, v_2) \leq (x, y)} \left[ \int_0^1 \frac{1}{2\pi f(2\pi s)} e^{-\frac{v_1^2+v_2^2}{4(2\pi f(2\pi s))}} ds \right] dv_1 dv_2.$$ (3.2)

Further, $F_C$ is bivariate normal if and only if $f$ is constant almost everywhere (Lebesgue).

(iv) If $\lambda(C_0) \neq 0$ then $F_C$ is discontinuous only on $D_1 = \{(x, y) : xy = 0\}$.
The proof of the Lemma is easy and we omit it. The asymptotic normality claim in (iii) follows by applying Cauchy-Schwartz inequality to compare fourth moment and square of the variance and using the fact that for the normal distribution their ratio equals 3. We omit the details.

**Theorem 1.** Suppose Assumptions B and C hold. Then the ESD of $C_n$ converges in $L_2$ to $F_C(\cdot)$ given in (3.1)–(3.2).

**Remark 1.** If $\{x_i\}$ are i.i.d with finite $(2 + \delta)$ moment, then $f(\omega) \equiv 1/2\pi$, and $F_C$ reduces to the bivariate normal distribution whose covariance matrix is diagonal with entries $1/2$ each. This agrees with Theorem 15, page 57 of Sen (2006) who proved the result under Assumption A.

### 3.2 Symmetric Circulant Matrix

For $x \in \mathbb{R}$ and $\omega \in [0, \pi]$ define,

$$H_S(\omega, x) = \begin{cases} \mathbb{P}(\sqrt{2\pi f(\omega)}N(0, 1) \leq x) & \text{if } f(\omega) \neq 0, \\ \mathbb{I}(x \geq 0) & \text{if } f(\omega) = 0. \end{cases}$$

(3.3)

As before, we now have the following Lemma.

**Lemma 2.** (i) For fixed $x$, $H_S$ is a bounded continuous function in $\omega$ and $H_S(\omega, x) + H_S(\omega, -x) = 1$.

(ii) $F_S$ defined below is a proper distribution function and $F_S(x) + F_S(-x) = 1$.

$$F_S(x) = 2 \int_0^{1/2} H_S(2\pi s, x)ds.$$  

(3.4)

(ii) If $\lambda(C_0) = 0$ then $F_S$ is continuous everywhere and may be expressed as

$$F_S(x) = \int_{-\infty}^{x} \left[ \int_0^{1/2} \frac{1}{\pi \sqrt{f(2\pi s)}} e^{-\frac{t^2}{4f(2\pi s)}} ds \right] dt.$$  

(3.5)

Further, $F_S$ is normal if and only if $f$ is constant almost everywhere (Lebesgue).

(iii) If $\lambda(C_0) \neq 0$ then $F_S$ is discontinuous only at $x = 0$.

**Theorem 2.** Suppose Assumptions B and C hold and

$$\lim_{n \to \infty} \frac{1}{n^2} \sum_{k=1}^{[n/2]^p} [f\left(\frac{2\pi k}{n}\right)]^{-3/2} \to 0 \quad \text{for all } 0 < p < 1.$$

(3.6)

Then the ESD of $SC_n$ converges in $L_2$ to $F_S$ given in (3.4)–(3.5). The same limit continues to hold for $PT_n$.

**Remark 2.** (i) (3.6) is satisfied if $\inf_{\omega} f(\omega) > 0$.

(ii) It is easy to check that the variance, $\mu_2$ and the fourth moment $\mu_4$ of $F_S$ equal $\int_0^{1/2} 4\pi f(2\pi s)ds$ and $\int_0^{1/2} 24\pi^2 f^2(2\pi s)ds$ respectively. By Cauchy-Schwartz inequality it follows that $\frac{\mu_4}{\mu_2^2} \geq 3$ and equal to 3 iff $f = \frac{1}{2\pi}$. In the latter case, $F_S$ is standard normal. This agrees with Remark 2 of Bose and Mitra (2002) (under Assumption A).
3.3 Reverse circulant matrix

Define $H_R(\omega, x)$ on $[0, 2\pi] \times \mathbb{R}$ as

$$H_R(\omega, x) = \begin{cases} G \left( \frac{x^2}{2\pi f(\omega)} \right) & \text{if } f(\omega) \neq 0 \\ 1 & \text{if } f(\omega) = 0, \end{cases}$$

where $G(x) = 1 - e^{-x}$ for $x > 0$, is the standard exponential distribution function.

**Lemma 3.** (i) For fixed $x$, $H_R(\omega, x)$ is bounded continuous on $[0, 2\pi]$.

(ii) $F_R$ defined below is a valid symmetric distribution function.

$$F_R(x) = \begin{cases} \frac{1}{2} + \int_0^{1/2} H_R(2\pi t, x) dt & \text{if } x > 0 \\ \frac{1}{2} - \int_0^{1/2} H_R(2\pi t, x) dt & \text{if } x \leq 0. \end{cases}$$  \hspace{1cm} (3.7)

(iii) If $\lambda(C_0) = 0$ then $F_R$ is continuous everywhere and can be expressed as

$$F_R(x) = \begin{cases} \frac{1}{2} - \int_0^{1} e^{-\frac{x^2}{2\pi f(\omega)}} dt & \text{if } x > 0 \\ \int_0^{1} e^{-\frac{x^2}{2\pi f(\omega)}} dt & \text{if } x \leq 0. \end{cases}$$  \hspace{1cm} (3.8)

Further, $F_R$ is the distribution of the symmetric version of the square root of chisquare variable with two degrees of freedom if and only if $f$ is constant almost everywhere (Lebesgue).

(iv) If $\lambda(C_0) \neq 0$ then $F_C$ is discontinuous only at $x = 0$.

**Theorem 3.** Suppose Assumptions B and C hold. Then the ESD of $RC_n$ converges in $L_2$ to $F_R$ given in (3.7)-(3.8).

**Remark 3.** If $\{x_i\}$ are i.i.d, with finite $(2 + \delta)$ moment, then $f(\omega) = 1/2\pi$ for all $\omega \in [0, 2\pi]$ and the LSD $F_R(\cdot)$ agrees with (1.2) given earlier.

3.4 $k$-Circulant Matrix

As mentioned before, it appears difficult to prove general results for all possible pairs $(k, n)$. We investigate two subclasses of the $k$-circulant.

3.4.1 $n = k^g + 1$ for some fixed $g \geq 2$

For any $d \geq 1$, let

$$G_d(x) = \mathbb{P}(\prod_{i=1}^{d} E_i \leq x),$$

where $\{E_i\}$ are i.i.d. $\text{Exp}(1)$. Note that $G_d$ is continuous. For any integer $d \geq 1$, define $H_d(\omega_1, \ldots, \omega_d, x)$ on $[0, 2\pi]^d \times \mathbb{R}_{\geq 0}$ as

$$H_d(\omega_1, \ldots, \omega_d, x) = \begin{cases} G_d \left( \frac{x^{2d}}{(2\pi)^d \prod_{i=1}^{d} f(\omega_i)} \right) & \text{if } \prod_{i=1}^{d} f(\omega_i) \neq 0 \\ 1 & \text{if } \prod_{i=1}^{d} f(\omega_i) = 0. \end{cases}$$
Lemma 4. (i) For fixed $x$, $H_d(\omega_1, \ldots, \omega_d, x)$ is bounded continuous on $[0, 2\pi]^d$.

(ii) $F_d$ defined below is a valid continuous distribution function.

$$F_d(x) = \int_0^1 \cdots \int_0^1 H_d(2\pi t_1, \ldots, 2\pi t_d, x) \prod_{i=1}^d dt_i$$ for $x \geq 0$. (3.9)

Theorem 4. Suppose Assumptions B and C hold. Suppose $n = k^g + 1$ for some fixed $g \geq 2$. Then as $n \to \infty$, $F_{n^{-1/2}A_n}$ converges in $L_2$ to the LSD $U_1(\prod_{i=1}^q E_i)^{1/2g}$ where $\{E_i\}$ are i.i.d. with distribution function $F_g$ given in (3.9) and $U_1$ is uniformly distributed over the $(2g)$th roots of unity, independent of the $\{E_i\}$.

Remark 4. If $\{x_i\}$ are i.i.d, then $f(\omega) = 1/2\pi$ for all $\omega \in [0, 2\pi]$ and the LSD is $U_1(\prod_{i=1}^q E_i)^{1/2g}$ where $\{E_i\}$ are i.i.d. Exp(1), $U_1$ is as in Theorem 4 and independent of $\{E_i\}$. This limit agrees with Theorem 3 of Bose, Mitra and Sen (2008).

Remark 5. Using the expression (2.8) for the characteristic polynomial, it is then not difficult to manufacture $\{k = \lambda(n)\}$ such that the LSD of $n^{-1/2}A_{k,n}$ has some positive mass at the origin. For example, suppose the sequences $k$ and $n$ satisfy $k^g = -1 + sn$ where $g \geq 1$ is fixed and $s = o(n^{1/3})$.

Fix primes $p_1, p_2, \ldots, p_t$ and positive integers $\beta_1, \beta_2, \ldots, \beta_t$. Define

$$\hat{n} = p_1^{\beta_1} p_2^{\beta_2} \cdots p_t^{\beta_t} n.$$ Suppose $k = p_1 p_2 \ldots p_t m \to \infty$. Then the ESD of $n^{-1/2}A_{k, \hat{n}}$ converges weakly in probability to the LSD which has $1 - \left(\prod_{i=1}^q p_i^{\beta_i}\right)^{-1}$ mass at zero, and rest of the probability mass is distributed as $U_1(\prod_{i=1}^q E_i)^{1/2g}$ where $U_1$ and $\{E_i\}$ are as in Theorem 4.

3.4.2 $n = k^g - 1$ for some $g \geq 2$

For $z_i, w_i \in \mathbb{R}, i = 1, 2, \ldots, g$, and with $\{N_i\}$ i.i.d. $N(0, 1)$, define

$$\mathcal{H}_g(\omega_1, z_i, w_i, i = 1, \ldots, g) = \mathbb{P}\left(B(\omega_1, \omega_2, \ldots, \omega_g)(N_1, \ldots, N_{2g}) \leq (z_i, w_i, i = 1, 2, \ldots, g)^t\right).$$

Lemma 5. (i) $\mathcal{H}_g$ is a bounded continuous in $(\omega_1, \ldots, \omega_g)$ for fixed $(z_i, w_i, i = 1, \ldots, g)$.

(ii) $\mathcal{F}_g$ defined below is a proper distribution function.

$$\mathcal{F}_g(z_i, w_i, i = 1, \ldots, g) = \int_0^1 \cdots \int_0^1 \mathcal{H}_g(2\pi t_1, z_i, w_i, i = 1, \ldots, g) \prod dt_i.$$ (3.10)

(iii) If $\lambda(C_0) = 0$ then $\mathcal{F}_g$ is continuous everywhere and may be expressed as

$$\mathcal{F}_g(z_i, w_i, i = 1, \ldots, g) = \int \cdots \int \mathbb{1}_{\{t \leq (z_i, w_i, k = 1, \ldots, g)\}} \left[ \int_0^1 \cdots \int_0^1 \frac{\mathbb{1}_{\{f(2\pi u_1) \neq 0\}}}{(2\pi)^g} \prod_{i=1}^g \mathbb{1}_{\{f(2\pi u_i) \neq 0\}} \prod_{i=1}^g e^{-\frac{1}{2} \frac{f^2(2\pi u_i)}{f(2\pi u_i)^2}} \prod du_i \right] dt.$$

where $t = (t_1, t_2, \ldots, t_{2g-1}, t_{2g})$ and $dt = \prod dt_i$. Further $\mathcal{F}_g$ is multivariate (with independent components) if and only if $f$ is constant almost everywhere (Lebesgue).

(iv) If $\lambda(C_0) \neq 0$ then $\mathcal{F}_g$ is discontinuous only on $D_g = \{(z_i, w_i, i = 1, \ldots, g) : \prod_{i=1}^g z_i w_i = 0\}$. 

10
Theorem 5. Suppose Assumptions B and C hold. Suppose \( n = k^g - 1 \) for some \( g \geq 2 \). Then as \( n \to \infty \), \( F_{n^{-1/2}A_{k,n}} \) converges in \( L_2 \) to the LSD \( (\prod_{i=1}^g G_i)^{1/g} \) where \( (R(G_i), I(G_i); \ i = 1, 2, \ldots g) \) has the distribution \( F_g \) given in (3.10).

Remark 6. If \( \{x_i\} \) are i.i.d. with finite \((2 + \delta)\) moment, then \( f(\omega) \equiv 1/2\pi \) and the LSD simplifies to \( U_2(\prod_{i=1}^g E_i)^{1/2g} \) where \( \{E_i\} \) are i.i.d. Exp(1), \( U_2 \) is uniformly distributed over the unit circle independent of \( \{E_i\} \). This agrees with Theorem 4 of Bose, Mitra and Sen (2008).

3.5 Simulations

To demonstrate the limits we did some modest simulations with MA(1) and MA(2) processes. We performed numerical integration to obtain the LSD. In case of \( k \)-circulant \( (n = k^2 + 1) \), we have plotted the density of \( F_2 \) defined in (3.9).

Figure 1: (i) (left) dashed line represents the density of \( F_2 \) when \( f(\omega) = \frac{1}{2\pi}(1.25 + \cos x) \) and the continuous line represents the same with \( f = \frac{1}{2\pi} \). (ii) (right) dashed line represents the LSD of symmetric circulant matrix with entries \( x_t = 0.3\epsilon_t + \epsilon_{t+1} + 0.5\epsilon_{t+2} \) where \( \{\epsilon_i\} \) i.i.d. \( N(0,1) \) and the continuous line represents the kernel density estimate of the ESD of the same matrix of order 5000 \( \times \) 5000 and same \( \{x_t\} \).

Figure 2: (i) (left) dashed line represents the LSD of the reverse circulant matrix with entries \( x_t = 0.3\epsilon_t + \epsilon_{t+1} + 0.5\epsilon_{t+2} \) where \( \{\epsilon_i\} \) i.i.d. \( N(0,1) \). The continuous line represents the kernel density estimate of ESD of the same matrix of order 5000 \( \times \) 5000 with same \( \{x_t\} \). (ii) same graphs with centered and scaled Binomial(1,0.5).
4 Proofs of main results

Throughout $c$ and $C$ will denote generic constants depending only on $d$. We use the notation $a_n \sim b_n$ if $a_n - b_n \to 0$ and $a_n \approx b_n$ if $\frac{a_n}{b_n} \to 1$. We use normal approximation heavily in our proofs. Lemma 6 is a fairly standard consequence of normal approximation and follows easily from Bhattacharya and Ranga Rao (1976) (Corollary 18.1, page 181 and Corollary 18.3, page 184). We omit its proof. Part (i) will be used in Section 4.1–4.4 and Part (ii) will be used in Section 4.4.

**Lemma 6.** Let $X_1, \ldots, X_k$ be independent random vectors with values in $\mathbb{R}^d$, having zero means and an average positive-definite covariance matrix $V_k = k^{-1} \sum_{j=1}^k \text{Cov}(X_j)$. Let $G_k$ denote the distribution of $k^{-1/2} T_k(X_1 + \ldots + X_k)$, where $T_k$ is the symmetric, positive-definite matrix satisfying $T_k^2 = V_k^{-1}$, $n \geq 1$. If for some $\delta > 0$, $\mathbb{E}\|X_j\|^{(2+\delta)} < \infty$, then there exists $C > 0$ (depending only on $d$), such that

(i) \[ \sup_{B \in \mathcal{C}} |G_k(B) - \Phi_d(B)| \leq C k^{-\delta/2} [\lambda_{\min}(V_k)]^{-(2+\delta)} \rho_{2+\delta} \]

(ii) for any Borel set $A$,

\[ |G_k(A) - \Phi_d(A)| \leq C k^{-\delta/2} [\lambda_{\min}(V_k)]^{-(2+\delta)} \rho_{2+\delta} + 2 \sup_{y \in \mathbb{R}^d} \Phi_d((\partial A)^\eta - y) \]

where $\Phi_d$ is the standard $d$ dimensional normal distribution function, $\mathcal{C}$ is the class of all Borel-measurable convex subsets of $\mathbb{R}^d$, $\rho_{2+\delta} = k^{-1} \sum_{j=1}^k \mathbb{E}\|X_j\|^{(2+\delta)}$ and $\eta = C \rho_{2+\delta} n^{-\delta/2}$.

As pointed out earlier, to prove that $F_n$ converges to $F$ (say) in $L_2$, it is enough to show that

$\mathbb{E}[F_n(t)] \to F(t)$ and $\mathbb{V}[F_n(t)] \to 0$ \hspace{1cm} (4.1)

at all continuity points $t$ of $F$. This is what we shall show in every case.

4.1 Proof of Theorem 1

The proof for circulant matrix mainly depends on Lemma 6 which helps to use normal approximation and, Lemma 7 given below which allows us to approximate the eigenvalues by appropriate partial sums of independent random variables. The latter follows easily from Fan and Yao (2003) (Theorem 2.14(ii), page 63). We have provided a proof in Appendix for completeness. For $k = 1, 2, \cdots, n$, define

$\xi_{2k-1} = \frac{1}{\sqrt{n}} \sum_{t=0}^{n-1} \epsilon_t \cos(\omega_k t)$, \hspace{0.5cm} $\xi_{2k} = \frac{1}{\sqrt{n}} \sum_{t=0}^{n-1} \epsilon_t \sin(\omega_k t)$.

**Lemma 7.** Suppose Assumption $B$ holds and $\{\epsilon_t\}$ are i.i.d random variables with mean 0, variance 1. Then for $k = 1, 2, \cdots, n$,

$\lambda_k = \frac{1}{\sqrt{n}} \sum_{t=0}^{n-1} x_t e^{i \omega_k t} = a(e^{i \omega_k})[\xi_{2k-1} + i \xi_{2k}] + Y_n(\omega_k),$

and $\max_{0 \leq k < n} \mathbb{E}|Y_n(\omega_k)|^2 \to 0$ as $n \to \infty$. 

12
Proof of Theorem 1: We first assume $\lambda(C_0) = 0$. Note that we may ignore the eigenvalue $\lambda_n$ and also $\lambda_{n/2}$ whenever $n$ is even since they contribute at most $2/n$ to the ESD $F_n(x, y)$. So for $x, y \in \mathbb{R}$,

$$\mathbb{E}[F_n(x, y)] \sim n^{-1} \sum_{k=1, k \neq n/2}^{n-1} \mathbb{P}(b_k \leq x, c_k \leq y).$$

Define for $k = 1, 2, \cdots, n$,

$$\eta_k = (\xi_{2k-1}, \xi_{2k})', \quad Y_1n(\omega_k) = \mathcal{R}[Y_n(\omega_k)], \quad Y_2n(\omega_k) = \mathcal{I}[Y_n(\omega_k)],$$

where $Y_n(\omega_k)$ are same as defined in Lemma 7. Then $(b_k, c_k)' = B(\omega_k)\eta_k + (Y_1n(\omega_k), Y_2n(\omega_k))'$. From Lemma 7, it is intuitively clear that for large $n$, $\lambda_k \sim a(e^{i\omega_k})[\xi_{2k-1} + i\xi_{2k}]$. So first we show that for large $n$

$$\frac{1}{n} \sum_{k=1, k \neq n/2}^{n-1} \mathbb{P}(b_k \leq x, c_k \leq y) \sim \frac{1}{n} \sum_{k=1, k \neq n/2}^{n-1} \mathbb{P}(B(\omega_k)\eta_k \leq (x, y)').$$

Note that the absolute difference of the above equals

$$\left| \frac{1}{n} \sum_{k=1, k \neq n/2}^{n-1} \mathbb{P}(B(\omega_k)\eta_k + (Y_1n(\omega_k), Y_2n(\omega_k))' \leq (x, y)') - \mathbb{P}(B(\omega_k)\eta_k \leq (x, y)') \right|$$

$$\leq \frac{1}{n} \sum_{k=1, k \neq n/2}^{n-1} \left[ \mathbb{P}(|Y_1n(\omega_k)| > \epsilon) + \mathbb{P}(|Y_2n(\omega_k)| > \epsilon) \right]$$

$$+ \frac{1}{n} \sum_{k=1, k \neq n/2}^{n-1} \left[ \mathbb{P}(B(\omega_k)\eta_k + (Y_1n(\omega_k), Y_2n(\omega_k))' \leq (x, y)', (|Y_1n(\omega_k)|, |Y_2n(\omega_k)|) \leq (\epsilon, \epsilon)) - \mathbb{P}(B(\omega_k)\eta_k \leq (x, y)') \right]$$

$$= T_1 + T_2,$$

say.

Using Lemma 7, as $n \to \infty$,

$$T_1 \leq \frac{2}{n} \sum_{k=1, k \neq n/2}^{n-1} \mathbb{P}(|Y_n(\omega_k)|^2 > \epsilon^2) \leq \frac{2}{\epsilon^2} \sup_k \mathbb{E}|Y_n(\omega_k)|^2 \to 0.$$

On the other hand, $T_2 \leq \max \{ R_{n1}, R_{n2} \}$ where

$$R_{n1} = \left| \frac{1}{n} \sum_{k=1, k \neq n/2}^{n-1} \mathbb{P}(B(\omega_k)\eta_k \leq (x + \epsilon, y + \epsilon)') - \mathbb{P}(B(\omega_k)\eta_k \leq (x, y)') \right|,$$

$$R_{n2} = \left| \frac{1}{n} \sum_{k=1, k \neq n/2}^{n-1} \mathbb{P}(B(\omega_k)\eta_k \leq (x - \epsilon, y - \epsilon)') - \mathbb{P}(B(\omega_k)\eta_k \leq (x, y)') \right|.$$

Note that $R_{n1} \leq T_3 + T_4 + T_5$ where with $N_1, N_2$ being independent standard normal variates,

$$T_3 = \left| \frac{1}{n} \sum_{k=1, k \neq n/2}^{n-1} \mathbb{P}(B(\omega_k)\eta_k \leq (x, y)') - \mathbb{P}(B(\omega_k)(N_1, N_2)' \leq (\sqrt{2}x, \sqrt{2}y)') \right|,$$
\[ T_4 = \left| \frac{1}{n} \sum_{k=1, k \neq n/2}^{n-1} \mathbb{P}(B(\omega_k)\eta_k \leq (x+\epsilon, y+\epsilon)) - \mathbb{P}(B(\omega_k)(N_1, N_2)' \leq (\sqrt{2}x+\sqrt{2}\epsilon, \sqrt{2}y+\sqrt{2}\epsilon)) \right|, \]

\[ T_5 = \left| \frac{1}{n} \sum_{k=1, k \neq n/2}^{n-1} \mathbb{P}(B(\omega_k)(N_1, N_2)' \leq (\sqrt{2}x+\sqrt{2}\epsilon, \sqrt{2}y+\sqrt{2}\epsilon)) - \mathbb{P}(B(\omega_k)(N_1, N_2)' \leq (\sqrt{2}x, \sqrt{2}y)) \right| \]

To show \( T_3, T_4 \to 0 \), define for \( 1 \leq k \leq n-1 \), (except for \( k = n/2 \)) and \( 1 \leq l \leq n-1 \),

\[ X_{l,k} = (\sqrt{2}e_l \cos(\omega_kl), \sqrt{2}e_l \sin(\omega_kl))'. \]

Note that

\[ \mathbb{E}(X_{l,k}) = 0 \] (4.2)

\[ n^{-1} \sum_{l=0}^{n-1} \text{Cov}(X_{l,k}) = I \] (4.3)

\[ \sup_{n} \sup_{1 \leq k \leq n} \left[ n^{-1} \sum_{l=0}^{n-1} \mathbb{E} \|X_{l,k}\|^{2+\delta} \right] \leq C < \infty. \] (4.4)

For \( k \neq n/2 \)

\[ \{B(\omega_k)\eta_k \leq (x, y)')\} = \{B(\omega_k)(n^{-1/2} \sum_{l=0}^{n-1} X_{l,k}) \leq (\sqrt{2}x, \sqrt{2}y)')\}. \]

Since \( \{(r, s) : B(\omega_k)(r, s)' \leq (\sqrt{2}x, \sqrt{2}y)')\} \) is a convex set in \( \mathbb{R}^2 \) and \( \{X_{l,k}, l = 0, 1, \ldots (n-1)\} \) satisfies (4.2)–(4.4), we can apply Part (i) of Lemma 6 for \( k \neq n/2 \) to get

\[ \left| \mathbb{P}(B(\omega_k)(n^{-1/2} \sum_{l=0}^{n-1} X_{l,k}) \leq (\sqrt{2}x, \sqrt{2}y)') - \mathbb{P}(B(\omega_k)(N_1, N_2)' \leq (\sqrt{2}x, \sqrt{2}y))' \right| \]

\[ \leq Cn^{-\delta/2}[n^{-1} \sum_{l=0}^{n-1} \mathbb{E} \|X_{l,k}\|^{2+\delta}] \leq Cn^{-\delta/2} \]

and hence as \( n \to \infty \), \( T_3 \leq Cn^{-\delta/2} \to 0 \). Similarly \( T_4 \to 0 \). Further

\[ \lim_{n \to \infty} \frac{1}{n} \sum_{k=1, k \neq n/2}^{n-1} \mathbb{P}(B(\omega_k)\eta_k \leq (x, y)) = \lim_{n \to \infty} \frac{1}{n} \sum_{k=1, k \neq n/2}^{n-1} H_C(\frac{2\pi k}{n}, x, y) = \int_0^1 H_C(2\pi s, x, y) ds. \]

Therefore

\[ \lim_{n \to \infty} T_5 = \left| \int_0^1 H_C(2\pi s, x + \epsilon, y + \epsilon) ds - \int_0^1 H_C(2\pi s, x, y) ds \right| \]

\[ \leq \int_0^1 |H_C(2\pi s, x + \epsilon, y + \epsilon) - H_C(2\pi s, x, y)| ds. \]

Note that \( H_C \) is uniformly bounded and for fixed \( (x, y) \in \mathbb{R}^2 \) as \( \epsilon \to 0 \),

\[ |H_C(2\pi s, x + \epsilon, y + \epsilon) - H_C(2\pi s, x, y)| \to 0. \] (4.5)
So by DCT \( \lim_{n \to 0} \lim_{n \to \infty} T_5 = 0 \) and hence \( R_{n1} \to 0 \). Proceeding as above we can show that \( R_{n2} \to 0 \) and hence \( \lim_{n \to 0} \lim_{n \to \infty} T_2 = 0 \). Therefore as \( n \to \infty \),

\[
E[F_n(x, y)] \sim \frac{1}{n} \sum_{k=1,k \neq n/2}^{n-1} \mathbb{P}( (B(\omega_k)\eta_k \leq (x, y)') - \int_0^1 H_C(2\pi s, x, y)ds. \tag{4.6}
\]

Now, to show \( V[F_n(x, y)] \to 0 \), it is enough to show that

\[
\frac{1}{n^2} \sum_{k \neq k'; k, k' = 1}^n \text{Cov}(J_k, J_{k'}) = \frac{1}{n^2} \sum_{k \neq k'; k, k' = 1}^n [E(J_k, J_{k'}) - E(J_k)E(J_{k'})] \to 0. \tag{4.7}
\]

where for \( 1 \leq k \leq n \), \( J_k \) is the indicator that \( \{b_k \leq x, c_k \leq y\} \). Now as \( n \to \infty \),

\[
\frac{1}{n^2} \sum_{k \neq k'; k, k' = 1}^n E(J_k)E(J_{k'}) = \left[ \frac{1}{n} \sum_{k=1}^n E(J_k) \right]^2 - \frac{1}{n^2} \sum_{k=1}^n [E(J_k)]^2 \to \left[ \int_0^1 H_C(2\pi s, x, y)ds \right]^2.
\]

So to show (4.7), it is enough to show as \( n \to \infty \),

\[
\frac{1}{n^2} \sum_{k \neq k'; k, k' = 1}^n E(J_k, J_{k'}) \to \left[ \int_0^1 H_C(2\pi s, x, y)ds \right]^2.
\]

Along the lines of the proof used to show (4.6) one may now extend the vectors of two coordinates defined above to ones with four coordinates and proceed exactly as above to verify this. We omit the routine details. This completes the proof for the case \( \lambda(C_0) = 0 \).

When \( \lambda(C_0) \neq 0 \), we have to show (4.1) only on \( D_1^c \) (of Lemma 1). All the above steps in the proof will go through for all \( (x, y) \) in \( D_1^c \). Hence if \( \lambda(C_0) \neq 0 \), we have our required LSD. This completes the proof of Theorem 1. \( \square \)

### 4.2 Proof of Theorem 2

For convenience, we prove the result for symmetric circulant matrix only for odd \( n = 2m + 1 \). The even case follows by appropriate easy changes in the proof. The partial sum approximation now takes the following form. For the interested reader, we provide a proof in the Appendix.

**Lemma 8.** Suppose Assumption B holds and \( \{\epsilon_i\} \) are i.i.d random variables with mean 0, variance 1. Then for \( n = 2m + 1 \) and \( k = 1, 2, \cdots, m \),

\[
\frac{1}{\sqrt{n}} \sum_{t=1}^m x_t \cos \frac{2\pi kt}{n} = a_1(e^{\sqrt{n}k}) \frac{1}{\sqrt{n}} \sum_{t=1}^m \epsilon_t \cos \frac{2\pi kt}{n} - a_2(e^{\sqrt{n}k}) \frac{1}{\sqrt{n}} \sum_{t=1}^m \sin \frac{2\pi kt}{n} + Y_{n,k},
\]

where \( a_1(e^{\sqrt{n}k}) \), \( a_2(e^{\sqrt{n}k}) \) are same as defined in (2.3) and \( \max_{0 \leq k \leq m} \mathbb{E}(Y_{n,k})^2 \to 0 \) as \( n \to \infty \).

**Proof of Theorem 2:** As before, we first assume \( \lambda(C_0) = 0 \). Note that we may ignore the eigenvalue \( \lambda_0 \) since it contributes \( 1/n \) to the ESD \( F_n(\cdot) \). Further the term \( \frac{2m}{\sqrt{n}} \) can be ignored from the eigenvalue \( \{\lambda_k\} \). So for \( x \in \mathbb{R} \),

\[
E[F_n(x)] \sim \frac{2}{n} \sum_{k=1}^m \mathbb{P}( \frac{1}{\sqrt{n}} \lambda_k \leq x ) = \frac{2}{n} \sum_{k=1}^m \mathbb{P}( \frac{1}{\sqrt{n}} \sum_{t=1}^m x_t \cos \frac{2\pi kt}{n} \leq x ).
\]

15
Following the argument given in circulant case and using Lemma 8 we can show that

\[
\mathbb{E}[F_n(x)] \sim \frac{2}{n} \sum_{k=1}^{m} \mathbb{P} \left[ a_1(e^{i\omega_k}) \frac{2}{n} \sum_{l=1}^{m} \epsilon_l \cos \frac{2\pi k}{n} \right. \\
- a_2(e^{i\omega_k}) \frac{2}{\sqrt{n}} \sum_{l=1}^{m} \sin \frac{2\pi k}{n} \leq x \right]\]

(4.8)

\[
= \frac{2}{n} \sum_{l=1}^{m} \mathbb{P} \left\{ m^{-1/2} \sum_{l=1}^{m} X_{l,k} \in C_k \right\}
\]

(4.9)

where

\[
X_{l,k} = (2\sigma_n^{-1} \epsilon_l \cos \frac{2\pi k}{n}, 2\delta_n^{-1} \epsilon_l \sin \frac{2\pi k}{n}), \quad \sigma_n^2 = 2 - 1/m, \quad \delta_n^2 = 2 + 1/m,
\]

(4.10)

\[
C_k = \{(u,v) : \sigma_n a_1(e^{i\omega_k}) u + \delta_n a_2(e^{i\omega_k}) v \leq \sqrt{n/m} \}.
\]

(4.11)

Note that

\[
\mathbb{E}(X_{l,k}) = 0, \quad \frac{1}{m} \sum_{l=1}^{m} \text{Cov}(X_{l,k}) = V_k \quad \text{and} \quad \sup_{m} \sup_{1 \leq k \leq m} m^{-1} \sum_{l=1}^{m} \mathbb{E}[X_{l,k}]^2 \leq C < \infty
\]

(4.12)

where

\[
V_k = \left( \begin{array}{cc} -1 & -1 \\ 1 & 1 \end{array} \right) \tan \frac{k\pi}{2m+1} - \frac{1}{\sqrt{4m^2 - 1}} \tan \frac{k\pi}{2m+1}.
\]

Let \(\alpha_k\) be the minimum eigenvalue of \(V_k\). Then \(\alpha_k \geq \alpha_m\) for \(1 \leq k \leq m\) and

\[
\alpha_m = 1 - \frac{1}{\sqrt{4m^2 - 1}} \tan \frac{m\pi}{2m+1} \approx 1 - \frac{2m + 1}{m\pi} \approx 1 - \frac{2}{\pi} = \alpha, \text{ say}.
\]

Since \(\{X_{l,k}\}\) satisfies (4.12) and \(C_k\) is a convex set in \(\mathbb{R}^2\), we can apply Part (i) of Lemma 6 for \(k = 1, 2, \cdots, m\) to get

\[
\left\{ \frac{2}{n} \sum_{k=1}^{m} \mathbb{P} \left\{ m^{-1/2} \sum_{l=1}^{m} X_{l,k} \in C_k \right\} - \Phi_{0,V_k}(C_k) \right\} \leq C m^{-\delta/2} \alpha^{3/2} \leq C m^{-\delta/2} \alpha^{3/2} \to 0.
\]

(4.13)

where \(\Phi_{0,V_k}\) is a bivariate normal distribution with mean zero and covariance matrix \(V_k\). Note that for large \(m\), \(\sigma_n^2 \approx 2\) and \(\delta_n^2 \approx 2\). Hence \(C_k' = \{(u,v) : a_1(e^{i\omega_k}) u + a_2(e^{i\omega_k}) v \leq \sqrt{x}\}\) serves as a good approximation to \(C_k\) and we get

\[
\frac{2}{n} \sum_{k=1}^{m} \mathbb{P}(\Phi_{0,V_k}(C_k) < \Phi_{0,V_k}(C_k')) = \frac{2}{n} \sum_{k=1}^{m} \mathbb{P}(\mu_k N(0,1) \leq x),
\]

(4.14)

where \(\mu_k^2 = a_1(e^{i\omega_k})^2 + a_2(e^{i\omega_k})^2\). Define \(\nu_k^2 = a_1(e^{i\omega_k})^2 + a_2(e^{i\omega_k})^2\). Now we show that

\[
\lim_{n \to \infty} \frac{2}{n} \sum_{k=1}^{m} \left[ \mathbb{P}(\mu_k N(0,1) \leq x) - \mathbb{P}(\nu_k N(0,1) \leq x) \right] = 0.
\]

(4.14)

Let \(0 < p < 1\). Now as \(n \to \infty\), using Assumption (3.6),

\[
\frac{2}{n} \left| \sum_{k=1}^{[mp]} \left[ \mathbb{P}(\mu_k N(0,1) \leq x) - \mathbb{P}(\nu_k N(0,1) \leq x) \right] \right| = \frac{2}{n} \left| \sum_{k=1}^{[mp]} \left[ \int_{x/\mu_k}^{x/\nu_k} \frac{1}{\sqrt{2\pi}} e^{-t^2} dt \right] \right|
\]

16
\[
\frac{2}{n} \sum_{k=1}^{[mp]} \left| \frac{x}{\mu_k} - \frac{x}{\nu_k} \right| 
\leq \frac{2|x|}{n} \sum_{k=1}^{[mp]} \left| \frac{\mu_k^2 - \nu_k^2}{\mu_k \nu_k (\mu_k + \nu_k)} \right| 
\leq \frac{2|x| \tan \pi}{m^2} \sum_{k=1}^{[mp]} \frac{1}{\nu_k^2 \alpha (1 + \alpha)} \to 0.
\]

On the other hand, for every \( n \),
\[
\left| \frac{2}{n} \sum_{k=1}^{m} \left[ \mathbb{P}(\mu_k N(0, 1) \leq x) - \mathbb{P}(\nu_k N(0, 1) \leq x) \right] \right| \leq 4(1 - p).
\]

Therefore, by first letting \( n \to \infty \) and then letting \( p \to 1 \), (4.14) holds. Hence
\[
\lim_{n \to \infty} \frac{2}{n} \sum_{k=1}^{[mp]+1} \mathbb{P}(\nu_k N(0, 1) \leq x) = \lim_{n \to \infty} \frac{2}{n} \sum_{k=1}^{[mp]} \mathbb{P}(\sqrt{2\pi f(2\pi k/n)} N(0, 1) \leq x) \to 2 \int_0^{1/2} H_S(2\pi s, x) ds.
\]

Rest of the argument in the proof for symmetric circulant is same as in the proof of Theorem 1.

To prove the result for \( PT_n \), we use Cauchy’s interlacing inequality (see Bhatia, 1997, page 59):

**Interlacing inequality:** Suppose \( A \) is an \( n \times n \) symmetric real matrix with eigenvalues \( \lambda_n \geq \lambda_{n-1} \geq \ldots \geq \lambda_1 \). Let \( B \) be the \((n - 1) \times (n - 1)\) principal submatrix of \( A \) with eigenvalues \( \mu_{n-1} \geq \ldots \geq \mu_1 \). Then
\[
\lambda_n \geq \mu_{n-1} \geq \lambda_{n-1} \geq \mu_{n-2} \geq \ldots \geq \lambda_2 \geq \mu_1 \geq \lambda_1.
\]

As a consequence
\[
\|FA - FB\|_\infty \leq \frac{1}{n}
\]
where \( FA \) denote the ESD of the matrix \( A \) and \( \|f\|_\infty = \sup_x |f(x)| \). We have already observed that the \( n \times n \) principal minor of \( PT_{n+1} \) is \( SC_n \). The result for \( PT_n \) follows immediately.

**4.3 Proof of Theorem 3**

For reverse circulant we need the following Lemma. Its proof is given in Fan and Yao (2003) (Theorem 2.14(ii), page 63).

**Lemma 9.** Suppose Assumption \( B \) holds and \( \{\epsilon_t\} \) are i.i.d random variables with mean 0, variance 1. Then for \( k = 1, 2, \ldots, \left[ \frac{n-1}{2} \right] \),
\[
I_n(\omega_k) = L_n(\omega_k) + R_n(\omega_k), \text{ where } L_n(\omega_k) = 2\pi f(\omega_k)(\xi_{2k-1}^2 + \xi_{2k}^2)
\]
and as \( n \to \infty \), \( \max_{1 \leq k \leq \left[ \frac{n-1}{2} \right]} \mathbb{E}|R_n(\omega_k)| \to 0. \)
Proof of Theorem 3: As earlier, we first assume \( \lambda(C_0) \neq 0 \). From the structure of the eigenvalues, the LSD, if it exists, is going to be that of a symmetric distribution. So, it is enough to concentrate on the case \( x > 0 \). As before we may ignore the two eigenvalues \( \lambda_0 \) and \( \lambda_{n/2} \). Hence for \( x > 0 \),

\[
E[F_n(x)] \sim 1/2 + n^{-1} \sum_{k=1}^{\lfloor n/2 \rfloor} P(I_n(\omega_k) \leq x^2). \tag{4.15}
\]

Along the same lines as in the proof of Theorem 1, using Lemma 9 we have

\[
\frac{1}{n} \sum_{k=1}^{\lfloor n/2 \rfloor} P(L_n(\omega_k) \leq x^2) \sim \frac{1}{n} \sum_{k=1}^{\lfloor n/2 \rfloor} P(L_n(\omega_k) \leq x^2),
\]

where

\[
L_n(\omega_k) = 2\pi f(\omega_k)(\xi_{2k-1}^2 + \xi_{2k}^2) \quad \text{for} \quad 1 \leq k \leq \lfloor n/2 \rfloor.
\]

Define for \( k = 1, 2, \ldots, \lfloor n/2 \rfloor \) and \( l = 0, 1, 2, \ldots, n-1 \),

\[
X_{l,k} = (\sqrt{2} \epsilon_l \cos(l\omega_k), \sqrt{2} \epsilon_l \sin(l\omega_k))', \quad A_{kn} = \{(r_1, r_2) : \pi f(\omega_k)(r_1^2 + r_2^2) \leq x^2\}.
\]

Note that \( \{X_{l,k}\} \) satisfies (4.2)– (4.4). Further

\[
\{L_n(\omega_k) \leq x^2\} = \{n^{-1/2} \sum_{l=0}^{n-1} X_{l,k} \in A_{kn}\}.
\]

Since \( A_{kn} \) is a convex set in \( \mathbb{R}^2 \), we can apply Part (i) of Lemma 6 to get, as \( n \to \infty \).

\[
\frac{1}{n} \sum_{k=1}^{\lfloor n/2 \rfloor} ||P(L_n(\omega_k) \leq x^2) - \Phi_{0,l}(A_{kn})|| \leq Cn^{-\delta/2} \to 0.
\]

But

\[
\frac{1}{n} \sum_{k=1}^{\lfloor n/2 \rfloor} \Phi_{0,l}(A_{kn}) = \frac{1}{n} \sum_{k=1}^{\lfloor n/2 \rfloor} H_R(2\pi k, x) \to \int_0^{1/2} H_R(2\pi t, x) dt.
\]

Hence for \( x \geq 0 \),

\[
E[F_n(x)] \rightarrow \frac{1}{2} + \int_0^{1/2} H_R(2\pi t, x) dt = F_R(x).
\]

Now rest of the argument in the proof is same as in the proof of Theorem 1.

\[\square\]

4.4 Proofs for Theorems 4 and 5

The proofs of the two theorems for \( k \) circulant matrices draw substantially from the method of Bose and Mitra (2002) and uses the eigenvalue description given earlier.
4.4.1 \( n = k^g + 1 \) for some fixed \( g \geq 2 \)

Proof of Theorem 4: For simplicity we first prove the result when \( g = 2 \). Note that \( \gcd(k,n) = 1 \) and hence in this case \( n' = n \) in (2.8). Thus the index of each eigenvalue belongs to exactly one of the sets \( P_l \) in the eigenvalue partition of \( \{0, 1, 2, ..., n-1\} \). Recall that \( v_{k,n} \) is the total number of eigenvalues \( \gamma_j \) of \( A_{k,n} \) such that \( j \in P_l \) and \( |P_l| < g_1 \). In view of Lemma 7 of Bose, Mitra and Sen (2008), we have \( v_{k,n}/n \leq 2/n \rightarrow 0 \) and hence these eigenvalues do not contribute to the LSD. Hence it remains to consider only the eigenvalues corresponding to the sets \( P_l \) which have size exactly equal to \( g_1 \).

It also follows from the argument in the proof of Lemma 3(i) of Bose, Mitra and Sen (2008) that \( g_1 = 4 \). Recall the quantities \( n_j = |P_j| \), \( y_j = \prod_{t \in P_j} \lambda_t \), where \( \lambda_j = \sum_{l=0}^{n-1} x_l \nu^j \), \( 0 \leq j < n \) given in (2.5). Also, for every integer \( t \geq 0 \), \( tk^2 = -t \mod n \), so that, \( \lambda_t \) and \( \lambda_{n-t} \) belong to the same partition block \( S(t) = S(n-t) \). Thus each \( y_t \) is real. Let us define

\[
I_n = \{ t : |P_t| = 4 \}.
\]

It is clear that \( n/|I_n| \rightarrow 4 \). Without any loss, let \( I_n = \{1, 2, ..., |I_n|\} \).

Let \( 1, \omega, \omega^2, \omega^3 \) be all the fourth roots of unity. Note that for every \( j \), the eigenvalues of \( A_{k,n} \) corresponding to the set \( P_j \) are: \( y_j^{1/4}, y_j^{1/4}, y_j^{1/4}, y_j^{1/4} \). Hence it suffices to consider only the modulus of eigenvalues \( y_j^{1/4} \) as \( j \) varies: if these have an LSD \( F \), say, then the LSD of the whole sequence will be \((r, \theta)\) in polar coordinates where \( r \) is distributed according to \( F \) and \( \theta \) is distributed uniformly across all the fourth roots of unity and \( r \) and \( \theta \) are independent. With this in mind and remembering the scaling \( \sqrt{n} \), we consider for \( x > 0 \),

\[
F_n(x) = |I_n|^{-1} \sum_{i=1}^{|I_n|} \mathbb{P}\left( \left( \frac{y_j}{n^2} \right)^{1/4} \leq x \right).
\]

Since the set of \( \lambda \) values corresponding to any \( P_j \) is closed under conjugation, there exists a set \( A_i \subset P_i \) of size 2 such that

\[
P_i = \{ x : x \in A_i \text{ or } n-x \in A_i \}.
\]

Combining each \( \lambda_j \) with its conjugate, we may write \( y_j \) in the form,

\[
y_j = \prod_{t \in A_j} (nb_t^2 + nc_t^2)
\]

where \( \{b_t\} \) and \( \{c_t\} \) are given in (2.4). Note that for \( x > 0 \),

\[
\mathbb{E}[F_n(x)] = |I_n|^{-1} \sum_{j=1}^{|I_n|} \mathbb{P}\left( \frac{y_j}{n^2} \leq x^4 \right).
\]

Define

\[
y_j = \prod_{t \in A_j} (n\xi_{2t-1}^2 + n\xi_{2t}^2) \quad \text{and} \quad f_j = \prod_{t \in A_j} f(\omega_t), \quad 1 \leq j \leq |I_n|.
\]

Let \( A_j = \{j_1, j_2\} \). From Lemma 9, it is intuitively clear that for large \( n \), \( y_j/n^2 \sim 4\pi^2 f_j \bar{y}_j/n^2 \). So first we show that for large \( n \),

\[
\frac{1}{|I_n|} \sum_{k=1}^{|I_n|} \mathbb{P}\left( \frac{y_j}{n^2} \leq x^4 \right) \sim \frac{1}{|I_n|} \sum_{k=1}^{|I_n|} \mathbb{P}(4\pi^2 f_j \bar{y}_j/n^2 \leq x^4).
\]
Let $\frac{y_j}{n^2} = L_{n,j} + R_{n,j}$ for $1 \leq j \leq |I_n|$, where

\[
L_{n,j} = 4\pi^2 f_j \frac{y_j}{n^2},
\]

\[
R_{n,j} = L_n(\omega_{j1})R_n(\omega_{j2}) + L_n(\omega_{j2})R_n(\omega_{j1}) + R_n(\omega_{j1})R_n(\omega_{j2})
\]

\[
L_n(\omega_{j}) = 2\pi f(\xi_{j1}^2 + \xi_{j2}^2), \quad k = 1, 2.
\]

Without loss we may choose $\epsilon$ small enough such that $x - \epsilon > 0$. Then

\[
\left| \sum_{k=1}^{|I_n|} \left[ \mathbb{P}(L_{n,j} + R_{n,j} \leq x^4) - \mathbb{P}(L_{n,j} \leq x^4) \right] \right| \leq \sum_{k=1}^{|I_n|} \mathbb{P}(|R_{n,j}| \geq \epsilon)
\]

\[
+ \sum_{k=1}^{|I_n|} \left| \mathbb{P}(L_{n,j} \leq x^4) - \mathbb{P}(L_{n,j} \leq x^4 + \epsilon) \right|
\]

\[
\leq |I_n|(T_1 + T_2 + T_3 + T_4), \quad \text{say},
\]

where

\[T_1 = \frac{1}{|I_n|} \sum_{j=1}^{|I_n|} \mathbb{P}(|R_{n,j}| \geq \epsilon), \quad T_2 = \frac{1}{|I_n|} \sum_{j=1}^{|I_n|} \left| \mathbb{P}(L_{n,j} \leq x^4) - \Phi_4(A_{n,j}) \right|,
\]

\[T_3 = \frac{1}{|I_n|} \sum_{j=1}^{|I_n|} \left| \mathbb{P}(L_{n,j} \leq x^4 + \epsilon) - \Phi_4(A_{n,j}^c) \right|, \quad T_4 = \frac{1}{|I_n|} \sum_{k=1}^{|I_n|} \left| \Phi_4(A_{n,j}) - \Phi_4(A_{n,j}^c) \right|,
\]

\[A_{n,j} = \{(a_1, b_1, a_2, b_2) : \prod_{i=1}^2 (a_i^2 + b_i^2) \leq \frac{x^4}{4\pi^2 f_j} \},
\]

\[A_{n,j}^c = \{(a_1, b_1, a_2, b_2) : \prod_{i=1}^2 (a_i^2 + b_i^2) \leq \frac{x^4 \pm \epsilon}{4\pi^2 f_j} \}.
\]

Note that $x > 0$ and without loss we may choose $\epsilon$ small enough such that $x^4 - \epsilon > 0$. It may be noted that if $f_j = 0$ for any $j$, then $A_{n,j}^c$ and $A_{n,j}$ are the whole spaces. We first show that $T_1 \to 0$ as $n \to \infty$. Now

\[
\mathbb{P}(|R_{n,j}| \geq \epsilon) \leq \mathbb{P}(|L_n(\omega_{j1})R_n(\omega_{j2})| \geq \epsilon/3) + \mathbb{P}(|L_n(\omega_{j2})R_n(\omega_{j1})| \geq \epsilon/3)
\]

\[
+ \mathbb{P}(|R_n(\omega_{j1})R_n(\omega_{j2})| \geq \epsilon/3).
\]

and

\[
\mathbb{P}(|R_n(\omega_{j1})R_n(\omega_{j2})| \geq \epsilon/3) \leq \frac{3}{\epsilon} \mathbb{P}(|R_n(\omega_{j1})| \geq \epsilon/3) + \mathbb{P}(|R_n(\omega_{j2})| \geq 1)
\]

\[
\leq \frac{3}{\epsilon} \mathbb{E}(|R_n(\omega_{j1})|) + \mathbb{E}(|R_n(\omega_{j2})|)
\]

Fix $M$ large. By Lemma 7, as $n \to \infty$

\[
\frac{1}{|I_n|} \sum_{j=0}^{|I_n|} \mathbb{P}(|R_n(\omega_{j1})R_n(\omega_{j2})| \geq \epsilon/3) \leq \left( \frac{3}{\epsilon} + 1 \right) \sup_{1 \leq j \leq \lceil \frac{y_j}{n^2} \rceil} \mathbb{E}|R_n(\omega_j)| \to 0.
\]

On the other hand,

\[
\mathbb{P}(|L_n(\omega_{j1})R_n(\omega_{j2})| \geq \epsilon/3) \leq \mathbb{P}(|L_n(\omega_{j1})| > \frac{\epsilon M}{3}) + \mathbb{P}(|R_n(\omega_{j2})| \geq \frac{1}{M})
\]

20
\[ \leq \frac{3}{M} \mathbb{E}(L_n(\omega_{j_1})) + M \mathbb{E}|R_n(\omega_{j_2})| \]

Note that sup_{1 \leq j \leq n} \mathbb{E}[L_n(\omega_{j_1})] \leq 4\pi \max_{\omega \in [0,2\pi]} f(\omega) < \infty. Hence

\[ \frac{1}{|I_n|} \sum_{j=0}^{|I_n|} \mathbb{P}(|L_n(\omega_{j_1})R_n(\omega_{j_2})| \geq \epsilon/3) \leq \frac{3}{M} 4\pi \max_{\omega \in [0,2\pi]} f(\omega) + M \sup_{1 \leq j \leq \frac{n-1}{2}} \mathbb{E}|R_n(\omega_j)| \]

Now if we first let \( n \to \infty \) and then let \( M \to \infty \), the right side of the above expression tends to zero. Therefore \( T_1 \to 0 \) as \( n \to \infty \).

We now show \( T_4 \leq C_2 \epsilon \) for any \( n \), where \( C_2 \) is a constant depending only on \( x \). It is understood that if \( f_j = 0 \) for any \( j \), then in the string of equations and inequalities below, that term is absent.

\[ T_4 = \frac{1}{|I_n|} \sum_{k=1}^{|I_n|} |\Phi_4(A_{n,j}) - \Phi_4(A_{n,j}^c)| \]

\[ \leq \frac{1}{|I_n|} \sum_{k=1}^{|I_n|} \left| \int_0^\infty \frac{1}{2} e^{-t/2} \left[ \int_{\frac{4}{2\pi f_j t}}^{\frac{4}{2\pi f_j t}} \frac{1}{2} e^{-s/2} ds \right] dt \right| \]

\[ \leq \frac{1}{|I_n|} \sum_{k=1}^{|I_n|} \left| \int_0^\infty \frac{1}{2} e^{-t/2} \left[ e^{-\frac{4}{2\pi f_j t}} - e^{-\frac{4}{2\pi f_j t}} \right] dt \right| \]

\[ \leq \int_0^\infty \frac{1}{2} e^{-t/2} \frac{1}{|I_n|} \sum_{k=1}^{|I_n|} e^{-\frac{4}{2\pi f_j t}} \frac{\epsilon}{2\pi f_j t} dt \]

\[ \leq \frac{\epsilon}{x^4}, \quad (\because e^{-\frac{4}{2\pi f_j t}} \leq \frac{1}{x^4}). \]

To show \( T_2, T_3 \to 0 \) we will use normal approximation. define

\[ X_{l,j} = 2^{1/2} \left( \epsilon_l \cos \left( \frac{2\pi t l}{n} \right), \quad \epsilon_l \sin \left( \frac{2\pi t l}{n} \right), \quad t \in A_j \right), \quad 0 \leq l < n, 1 \leq j \leq |I_n|. \]

Note that \( \{X_{l,j}\} \) satisfies (4.2)–(4.4) and

\[ \{4\pi^2 f_j \frac{\mathcal{Y}_j}{n^2} \leq x^4\} = \{n^{-1/2} \sum_{l=1}^{n-1} X_{l,j} \in A_{n,j}\}. \]

Now using Part (ii) of Lemma 6 and Lemma 4 of Bose, Mitra and Sen (2008), arguing as in the previous proofs,

\[ |I_n|^{-1} \sum_{l=1}^{|I_n|} \mathbb{P} \left( 4\pi^2 f_j \frac{\mathcal{Y}_j}{n^2} \leq x^4 \right) - \Phi_4(A_{n,j}) \to 0. \]

Hence \( T_2 \to 0 \) and similarly \( T_3 \to 0 \). Therefore

\[ \mathbb{E}[F_n(x)] = \frac{1}{|I_n|} \sum_{j=1}^{|I_n|} \mathbb{P} \left( \frac{\mathcal{Y}_j}{n^2} \leq x^4 \right) \sim \frac{1}{|I_n|} \sum_{j=1}^{|I_n|} \mathbb{P} \left( 4\pi^2 f_j \frac{\mathcal{Y}_j}{n^2} \leq x^4 \right) \sim \frac{1}{|I_n|} \sum_{j=1}^{|I_n|} \Phi_4(A_{n,j}). \]
To identify the limit, recall the structure of the sets \( S(x), P_j, A_j \) and their properties. Since \( |I_n|/n \to 1/4 \), \( v_{k,n} \leq 2 \) and either \( S(x) = S(u) \) or \( S(x) \cap S(u) = \phi \), we have

\[
\lim_{n \to \infty} \frac{1}{|I_n|} \sum_{j=1}^{[f_n]} \Phi_4(A_{n,j}) = \lim_{n \to \infty} \frac{1}{n} \sum_{j=1, |A_j|=2}^{n} \Phi_4(A_{n,j}) \tag{4.16}
\]

Also for \( n = k^2 + 1 \) we can write \( \{1, 2, \ldots, n-1\} \) as \( \{ak+b; 0 \leq a \leq k-1, 1 \leq b \leq k\} \) and using the construction of \( S(x) \) we have

\( A_j = \{ak+b, bk-a\} \) for \( j = ak+b; 0 \leq a \leq k-1, 1 \leq b \leq k \)

(except for at most two values of \( j \)).

Recall that for fixed \( x \), \( H_2(\omega, \omega', x) \) is uniformly continuous on \([0, 2\pi] \times [0, 2\pi] \). Therefore given any positive number \( \rho \) we can choose \( N \) large enough such that for all \( n = k^2 + 1 > N \),

\[
\sup_{0 \leq a \leq k-1, 1 \leq b \leq k} \left| H_2\left(\frac{2\pi(a+b)}{n}, \frac{2\pi(bk-a)}{n}, x\right) - H_2\left(\frac{2\pi a}{\sqrt{n}}, \frac{2\pi b}{\sqrt{n}}, x\right) \right| < \rho. \tag{4.17}
\]

Finally using (4.16), (4.17) we have

\[
\lim_{n \to \infty} \frac{1}{|I_n|} \sum_{j=1}^{[f_n]} \Phi_4(A_{n,j}) = \lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} \Phi_4(A_{n,j})
\]

\[
= \lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} G_2\left(\frac{x^4}{4\pi^2 f_j}\right)
\]

\[
= \lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} \sum_{b=1}^{\lfloor \sqrt{n} \rfloor} \sum_{a=0}^{\lfloor \sqrt{n} \rfloor} H_2\left(\frac{2\pi(a+b)}{n}, \frac{2\pi(bk-a)}{n}, x\right)
\]

\[
= \lim_{n \to \infty} \frac{1}{n} \sum_{b=1}^{\lfloor \sqrt{n} \rfloor} \sum_{a=0}^{\lfloor \sqrt{n} \rfloor} H_2\left(\frac{2\pi a}{\sqrt{n}}, \frac{2\pi b}{\sqrt{n}}, x\right)
\]

\[
= \int_0^1 \int_0^1 H_2(2\pi s, 2\pi t, x) ds \ dt = F_2(x).
\]

To show that \( V[F_n(x)] \to 0 \), since the variables involved are all bounded, it is enough to show that

\[
n^{-2} \sum_{j \neq j'} Cov \left( \mathbb{1}(\frac{y_j}{n^2} \leq x^4), \mathbb{1}(\frac{y_j'}{n^2} \leq x^4) \right) \to 0.
\]

Along the lines of the proof used to show \( \mathbb{E}[F_n(x)] \to F_2(x) \), one may now extend the vectors with 4 coordinates defined above to ones with 8 coordinates and proceed exactly as above to verify this.

We omit the routine details. This proves the Theorem when \( g = 2 \). The above argument can be extended to cover the general \( (g > 2) \) case. We highlight only a few of the technicalities and omit the other details. We now need the following lemma.

**Lemma 10.** Given any \( \epsilon, \eta > 0 \) there exist an \( N \in \mathbb{N} \) such that

\[
\mathbb{P}(\prod_{i=1}^{s} L_n(\omega_j_i) \prod_{i=s+1}^{g} R_n(\omega_j_i)) > \epsilon \leq \frac{2\pi}{M} (s-1+\frac{1}{\epsilon}) \max_{0 \leq \omega \leq 2\pi} f(\omega) + (M^s + g - s - 1) \max_{1 \leq k \leq n} \mathbb{E}|R_n(\omega_k)| < \eta
\]

for all \( n \geq N \), where \( L_n(\omega_j_i), R_n(\omega_j) \) are as defined in Lemma 9.
Proof. Note
\[ \mathbb{P}(\left| \prod_{i=1}^{s} L_n(\omega_{j_i}) \prod_{i=s+1}^{g} R_n(\omega_{j_i}) \right| > \epsilon) \leq \mathbb{P}(\left| L_n(\omega_{j_1}) \right| \geq M\epsilon) \]
\[ + \mathbb{P}(\left| \prod_{i=2}^{s} L_n(\omega_{j_i}) \prod_{i=s+1}^{g} R_n(\omega_{j_i}) \right| > 1/M), \]
and iterating this argument,
\[ \mathbb{P}(\left| \prod_{i=1}^{s} L_n(\omega_{j_i}) \prod_{i=s+1}^{g} R_n(\omega_{j_i}) \right| > \epsilon) \leq \mathbb{P}(\left| L_n(\omega_{j_1}) \right| \geq M\epsilon) + \sum_{i=2}^{s} \mathbb{P}(\left| L_n(\omega_{j_i}) \right| \geq M.) \]
\[ + \mathbb{P}(\left| \prod_{i=s+1}^{g} R_n(\omega_{j_i}) \right| > 1/M^s). \]
Also note that
\[ \mathbb{P}(\left| \prod_{i=s+1}^{g} R_n(\omega_{j_i}) \right| > 1/M^s) \leq \mathbb{P}(\left| \prod_{i=s+1}^{g} R_n(\omega_{j_i}) \right| > 1/M^s) + \mathbb{P}(\left| R_n(\omega_{j_{s+1}}) \right| > 1) \]
\[ \leq \mathbb{P}(\left| R_n(\omega_{j_s}) \right| > 1/M^s) + \sum_{i=1}^{g-1} \mathbb{P}(\left| R_n(\omega_{j_i}) \right| > 1) \]
\[ \leq (M^s + g - s - 1) \max_{1 \leq k \leq n} \mathbb{E}[R_n(\omega_k)]. \]
Combining all the above we get
\[ \mathbb{P}(\left| \prod_{i=1}^{s} L_n(\omega_{j_i}) \prod_{i=s+1}^{g} R_n(\omega_{j_i}) \right| > \epsilon) \leq \mathbb{P}(\left| L_n(\omega_{j_1}) \right| \geq M\epsilon) + \sum_{i=2}^{s} \mathbb{P}(\left| L_n(\omega_{j_i}) \right| \geq M) \]
\[ + (M^s + g - s - 1) \max_{1 \leq k \leq n} \mathbb{E}[R_n(\omega_k)] \]
\[ \leq \frac{1}{M}(s - 1 + 1/\epsilon)4\pi \max_{\omega \in [0,2\pi]} f(\omega) \]
\[ + (M^s + g - s - 1) \max_{1 \leq k \leq n} \mathbb{E}[R_n(\omega_k)]. \]
First term in the right side can be made smaller than \( \eta/2 \) by choosing \( M \) large enough and since \( \max_{1 \leq k \leq n} \mathbb{E}[R_n(\omega_k)] \to 0 \) as \( n \to \infty \), we can choose \( N \in \mathbb{N} \) such that the second term is less than \( \eta/2 \) for all \( n \geq N \), proving the lemma. \( \square \)

For general \( g \geq 2 \), as before, \( n' = n \), the index of each eigenvalue belongs to one of the sets \( \mathcal{P}_l \) in the eigenvalue partition of \( \{0, 1, 2, ..., n-1\} \) and \( v_{k,n}/n \to 0 \). Hence it remains to consider only the eigenvalues corresponding to the sets \( \mathcal{P}_l \) which have size exactly equal to \( g_1 \) and it follows from the argument in the proof of Lemma 3(i) of Bose, Mitra and Sen (2008) that \( g_1 = 2g \). We can now proceed as in \( g = 2 \) case. First we show
\[ \frac{1}{|I_n|} \sum_{j=1}^{I_n} \mathbb{P}(\frac{y_j}{n^g} \leq x^{2g}) \sim \frac{1}{|I_n|} \sum_{j=1}^{I_n} \mathbb{P}((2\pi)^g f_j \frac{y_j}{n^g} \leq x^{2g}). \]
Let
\[ \frac{y_j}{n^\gamma} = L_{n,j} + R_{n,j} \text{ for } 1 \leq j \leq |I_n|, \quad L_{n,j} = \prod_{t \in A_j} L_n(\omega_t) = (2\pi)^g f_j \frac{\eta_j}{n^\gamma}, \]
\[ A_{n,j} = \left\{ (a_i, b_i, i = 1, 2, \ldots, g) : \prod_{i=1}^{g} 2^{-1}(a_i^2 + b_i^2) \leq \frac{x^{2g}}{(2\pi)^g f_j} \right\}, \]
\[ A_{n,j}^c = \left\{ (a_i, b_i, i = 1, 2, \ldots, g) : \prod_{i=1}^{g} 2^{-1}(a_i^2 + b_i^2) \leq \frac{x^{2g} + \epsilon}{(2\pi)^g f_j} \right\}. \]

Note that
\[ \frac{1}{|I_n|} \sum_{j=1}^{|I_n|} |\Phi_{2g}(A_{n,j}) - \Phi_{2g}(A_{n,j}^c)| \leq \frac{1}{|I_n|} \sum_{j=1}^{|I_n|} \int_0^\infty h(t)[e^{-\frac{x^{2g}}{(2\pi)^g f_j t}} - e^{-\frac{x^{2g} + \epsilon}{(2\pi)^g f_j t}}] dt \]
\[ \leq \int_0^\infty h(t) \frac{1}{|I_n|} \sum_{k=1}^{|I_n|} e^{-\frac{x^{2g}}{(2\pi)^g f_j t}} \frac{\epsilon}{(2\pi)^g f_j t} dt \leq \frac{\epsilon}{x^{2g}}, \]

since \( e^{-\frac{x^{2g}}{(2\pi)^g f_j t}} \frac{1}{(2\pi)^g f_j} \leq \frac{1}{x^{2g}} \) and \( h(t) \) is the density function of product of \((g - 1)\) i.i.d. \( \text{Exp}(1) \).

Now by last observation, Lemma 10 and using normal approximation appropriately, we can show as \( n \to \infty \)
\[ \frac{1}{|I_n|} \sum_{j=1}^{|I_n|} P(L_{n,j} + R_{n,j} \leq x^{2g}) - \frac{1}{|I_n|} \sum_{k=1}^{|I_n|} P(L_{n,j} \leq x^{2g}) \to 0. \]

Now note that for \( n = k^g + 1 \) we can write \( \{1, 2, \ldots, n - 1\} \) as \( \{b_1 k^{-1} + b_2 k^{-2} + \cdots + b_{g-1} k + b_g : 0 \leq b_i \leq k - 1, \text{ for } 1 \leq i \leq k - 1; \text{ for } b_g \leq k \} \). So we can write the sets \( A_j \) explicitly using this decomposition of \( \{1, 2, \ldots, n - 1\} \) as done in \( g = 2 \) case, that is, \( n = k^g + 1 \) case. For example if \( g = 3 \), \( A_j = \{b_1 k^2 + b_2 k + b_3, b_2 k^2 + b_3 k - b_1, b_3 k^2 - b_1 k - b_2 \} \) for \( j = b_1 k^2 + b_2 k + b_3 \) (except for finitely many \( j \), bounded by \( v_{k,n} \) and they do not contribute to this limit). Using this fact and proceeding as before we conclude that the LSD is now \( F_g(\cdot) \), proving Theorem 4 completely. \( \square \)

4.4.2 \( n = k^g - 1 \) for some fixed \( g \geq 2 \)

Proof of Theorem 5. First we assume \( \lambda(C_0) = 0 \). Note that \( \gcd(k, n) = 1 \). Since \( k^g = 1 + n = 1 \mod n \), we have \( g_1 | g \). If \( g_1 < g \), then \( g_1 \leq g/\alpha \) where \( \alpha = 2 \) if \( g \) is even and \( \alpha = 3 \) if \( g \) is odd. In either case, it is easy to check that
\[ k^{g_1} \leq k^{g/\alpha} \leq (1 + n)^{1/\alpha} = o(n). \]

Hence, \( g = g_1 \). By Lemma 3(ii) of Bose, Mitra and Sen (2008) the total number of eigenvalues \( \gamma_j \) of \( A_{k,n} \) such that \( j \in A_l \) and \( |A_l| < g \) is asymptotically negligible.

Unlike the previous theorem, here the partition sets \( A_l \) are not necessarily self-conjugate. However, the number of indices \( l \) such that \( A_l \) is self-conjugate is asymptotically negligible compared to \( n \). To show this, we need to bound the cardinality of the following set for \( 1 \leq l < g \):
\[ D_l = \{ t \in \{1, 2, \ldots, n\} : tk^l = -t \mod n \} = \{ t \in \{1, 2, \ldots, n\} : n|t(k^l + 1) \}. \]

24
Note that $t_0 = n / \gcd(n, k^l + 1)$ is the minimum element of $D_l$ and every other element is a multiple of $t_0$. Thus

$$|D_l| \leq \frac{n}{t_0} \leq \gcd(n, k^l + 1).$$

Let us now estimate $\gcd(n, k^l + 1)$. For $l > \lfloor g/2 \rfloor$,

$$\gcd(n, k^l + 1) \leq \gcd(k^g - 1, k^l + 1) = g\gcd(k^{g-l}(k^l + 1) - (k^{g-l} - 1), k^l + 1) \leq k^{g-l},$$

which implies $\gcd(n, k^l + 1) \leq k^{\lfloor g/2 \rfloor}$ for all $1 \leq l < g$. Therefore,

$$\frac{\gcd(n, k^l + 1)}{n} = \frac{k^{\lfloor g/2 \rfloor}}{(k^g - 1)} \leq \frac{2}{k^{\lfloor (g+1)/2 \rfloor}} \leq \frac{2}{((n)^{1/g})^{\lfloor (g+1)/2 \rfloor}} = o(1).$$

So, we can ignore the partition sets $P_j$ which are self-conjugate. For other $P_j$,

$$y_j = \prod_{\ell \in P_j} (\sqrt{n}b_{\ell} + i\sqrt{n}c_{\ell})$$

will be complex.

Now for simplicity we will provide the detailed argument assuming that $g = 2$. Then, $n = k^2 - 1$ and we can write $\{0, 1, 2, \ldots, n\}$ as $\{ak+b : 0 \leq a \leq k-1, 0 \leq b \leq k-1\}$ and using the construction of $S(x)$ we have $P_j = \{ak+b, bk+a\}$ and $|P_j| = 2$ for $j = ak+b; 0 \leq a \leq k-1, 0 \leq b \leq k-1$ (except for finitely many $j$ and hence such indices do not contribute to the LSD). Let us define

$$I_n = \{l : |P_l| = 2\}.$$

It is clear that $n/|I_n| \to 2$. Without any loss, let $I_n = \{1, 2, \ldots, |I_n|\}$. Suppose $P_j = \{j_1, j_2\}$. We first find the limiting distribution of the empirical distribution of $\frac{1}{\sqrt{n}}(\sqrt{n}b_{j_1}, \sqrt{n}c_{j_1}, \sqrt{n}b_{j_2}, \sqrt{n}c_{j_2})$ for those $j$ for which $|P_j| = 2$ and show the convergence in $L_2$. Let $F_n(x, y, z, w)$ be the ESD of $\{(b_{j_1}, c_{j_1}, b_{j_2}, c_{j_2})\}$, that is

$$F_n(z_1, w_1, z_2, w_2) = \frac{2}{|I_n|} \sum_{j=1}^{|I_n|} \mathbb{I}(b_{j_k} \leq z_k, c_{j_k} \leq w_k, \ k = 1, 2).$$

We show that for $z_1, w_1, z_2, w_2 \in \mathbb{R}$,

$$\mathbb{E}[F_n(z_1, w_1, z_2, w_2)] \to F_2(z_1, w_1, z_2, w_2) \text{ and } \mathbb{V}[F_n(z_1, w_1, z_2, w_2)] \to 0. \quad (4.18)$$

Define for $k = 1, 2, \ldots, n$,

$$\eta_j = (\xi_{2j_1-1}, \xi_{2j_1}, \xi_{2j_2-1}, \xi_{2j_2}),$$

and let $Y_{1n}(\omega_j) = \mathcal{R}(Y_{1n}(\omega_j)), \ Y_{2n}(\omega_j) = \mathcal{I}(Y_{1n}(\omega_j))$, where $Y_{1n}(\omega_j)$ is same as defined in Lemma 7. Define

$$Y_{n,j} = (Y_{1n}(w_{j_1}), Y_{2n}(w_{j_1}), Y_{1n}(w_{j_2}), Y_{2n}(w_{j_2})), \ N = (N_1, N_2, N_3, N_4),$$

and

$$\mathbb{P}(|Y_{n,j}| \leq \epsilon) = \mathbb{P}(Y_{1n}(\omega_{j_1}) \leq \epsilon, Y_{2n}(\omega_{j_1}) \leq \epsilon, Y_{1n}(\omega_{j_2}) \leq \epsilon, Y_{2n}(\omega_{j_2}) \leq \epsilon),$$

where $\{N_i\}$ are i.i.d. $N(0, 1)$. Then $(b_{j_1}, c_{j_1}, b_{j_2}, c_{j_2}) = B(\omega_{j_1}, \omega_{j_2})\eta_j + Y'_{n,j}$. From Lemma 7, it is intuitively clear that for large $n, \ [b_{j_1} + ic_{j_1}] \sim a(e^\omega(i\xi_{2j_1-1} + i\xi_{2j_1}))$. Note that

$$\left| \frac{1}{|I_n|} \sum_{j=1}^{|I_n|} \mathbb{P}(b_{j_k} \leq z_k, c_{j_k} \leq w_k, \ k = 1, 2) - \frac{1}{|I_n|} \sum_{j=1}^{|I_n|} \mathbb{P}(B(\omega_{j_1}, \omega_{j_2})\eta_j \leq (z_1, w_1, z_2, w_2)) \right| = 25$$
Note that

To show

Now using Lemma 7, as $n \to \infty$

$$ T_1 \leq \frac{4}{|I_n|} \sum_{j=1}^{|I_n|} \mathbb{P}(|Y_n(\omega_{j1})|^2 > \epsilon^2) \leq \frac{4}{\epsilon^2} \sup_j \mathbb{E}|Y_n(\omega_{j1})|^2 \to 0. $$

$$ T_2 \leq \max \{ R_{n1}, R_{n2} \} $$

where

$$ R_{n1} = \frac{1}{|I_n|} \sum_{j=1}^{|I_n|} \left| \mathbb{P}(B(\omega_{j1}, \omega_{j2})\eta_j \leq (z_1, w_1, z_2, w_2)') - \mathbb{P}(B(\omega_{j1}, \omega_{j2})\eta_j \leq (z_1, w_1, z_2, w_2)') \right|,$$

$$ R_{n2} = \frac{1}{|I_n|} \sum_{j=1}^{|I_n|} \left| \mathbb{P}(B(\omega_{j1}, \omega_{j2})\eta_j \leq (z_1 - \epsilon, w_1 - \epsilon, z_2 - \epsilon, w_2 - \epsilon)') - \mathbb{P}(B(\omega_{j1}, \omega_{j2})\eta_j \leq (z_1, w_1, z_2, w_2)') \right|. $$

Note that $R_{n1} \leq T_3 + T_4 + T_5$ where

$$ T_3 = \frac{1}{|I_n|} \sum_{j=1}^{|I_n|} \left| \mathbb{P}(B(\omega_{j1}, \omega_{j2})\eta_j \leq (z_1, w_1, z_2, w_2)') - \mathbb{P}(B(\omega_{j1}, \omega_{j2})N \leq (\sqrt{2}z_1, \sqrt{2}w_1, \sqrt{2}z_2, \sqrt{2}w_2)') \right|, $$

$$ T_4 = \frac{1}{|I_n|} \sum_{j=1}^{|I_n|} \left| \mathbb{P}(B(\omega_{j1}, \omega_{j2})\eta_j \leq (z_k + \epsilon, w_k + \epsilon, k = 1, 2)') - \mathbb{P}(B(\omega_{j1}, \omega_{j2})N \leq (\sqrt{2}z_k + \sqrt{2}\epsilon, \sqrt{2}w_k + \sqrt{2}\epsilon, k = 1, 2)') \right|, $$

$$ T_5 = \frac{1}{|I_n|} \sum_{j=1}^{|I_n|} \left| \mathbb{P}(B(\omega_{j1}, \omega_{j2})N \leq (\sqrt{2}z_k, \sqrt{2}w_k, k = 1, 2)') - \mathbb{P}(B(\omega_{j1}, \omega_{j2})N \leq (\sqrt{2}z_k, \sqrt{2}w_k, k = 1, 2)') \right|. $$

To show $T_3, T_4 \to 0$, define

$$ X_{l,k} = 2^{1/2} \left( e_l \cos \left( \frac{2\pi j_1 l}{n} \right), e_l \sin \left( \frac{2\pi j_1 l}{n} \right), e_l \cos \left( \frac{2\pi j_2 l}{n} \right), e_l \sin \left( \frac{2\pi j_2 l}{n} \right) \right). $$

Note that $\{X_{l,j}\}$ satisfies (4.2) and (4.3) and

$$ \{ B(\omega_{j1}, \omega_{j2})\eta_j \leq (z_1, w_1, z_2, w_2)' \} = \{ B(\omega_{j1}, \omega_{j2})(n^{-1/2} \sum_{l=0}^{n-1} X_{l,j}) \leq (\sqrt{2}z_1, \sqrt{2}w_1, \sqrt{2}z_2, \sqrt{2}w_2)' \}. $$
Since \( \{(r_1, r_2, r_3, r_4) : B(\omega_{j_1}, \omega_{j_2})(r_1, r_2, r_3, r_4)' \leq (\sqrt{2}z_1, \sqrt{2}w_1, \sqrt{2}z_2, \sqrt{2}w_2)' \} \) is a convex set in \( \mathbb{R}^4 \) and \( \{X_{i,k} : i = 0, 1, \ldots, (n - 1) \} \) satisfies (4.2) and (4.3), we can show using Part (i) of Lemma 6 that \( T_3, T_4 \to 0 \) as \( n \to \infty \) and hence

\[
\lim_{n \to \infty} \frac{1}{|I_n|} \sum_{j=1}^{|I_n|} \mathbb{P}(B(\omega_{j_1}, \omega_{j_2})N \leq (\sqrt{2}z_1, \sqrt{2}w_1, \sqrt{2}z_2, \sqrt{2}w_2)') = \lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} \mathbb{P}(B(\omega_{j_1}, \omega_{j_2})N \leq (\sqrt{2}z_1, \sqrt{2}w_1, \sqrt{2}z_2, \sqrt{2}w_2)')
\]

\[
= \lim_{n \to \infty} \frac{1}{n} \sum_{j=1}^{n} \mathcal{H}_2(\omega_{j_1}, \omega_{j_2}, z_1, w_1, z_2, w_2)
\]

\[
= \lim_{n \to \infty} \frac{1}{n} \sum_{a=0}^{[\sqrt{n}]} \sum_{b=0}^{[\sqrt{n}]} \mathcal{H}_2(2\pi a n, 2\pi b n, z_1, w_1, z_2, w_2)
\]

\[
= \int_0^1 \int_0^1 \mathcal{H}_2(2\pi s, 2\pi t, z_1, w_1, z_2, w_2) ds dt.
\]

Further, arguing as in the proof of Theorem 1, \( \lim_{n \to \infty} T_5 = 0 \) and \( \lim_{\epsilon \to 0} \lim_{n \to \infty} R_{n1} = 0 \). Similarly \( \lim_{\epsilon \to 0} \lim_{n \to \infty} R_{n2} = 0 \) and hence \( \lim_{\epsilon \to 0} \lim_{n \to \infty} T_2 = 0 \). Therefore as \( n \to \infty \),

\[
\mathbb{E}[F_n(z_1, w_1, z_2, w_2)] = \frac{1}{|I_n|} \sum_{j=1}^{|I_n|} \mathbb{P}(B(\omega_{j_1}, \omega_{j_2})N \leq (z_1, w_1, z_2, w_2)')
\]

\[
\to \int_0^1 \int_0^1 \mathcal{H}_2(2\pi s, 2\pi t, z_1, w_1, z_2, w_2) ds dt.
\]

Similarly we can show \( V[F_n(x)] \to 0 \) as \( n \to \infty \).

Hence the empirical distribution of \( y_j \) for those \( j \) for which \( |\mathcal{P}_j| = 2 \) converges to the distribution of \( \prod_{i=1}^2 G_i \) such that \( (\mathcal{R}(G_i), \mathcal{I}(G_i); \ i = 1, 2) \) has distribution \( \mathcal{F}_2 \). Hence the LSD of \( n^{-1/2}A_{k,n} \) is \( (\prod_{i=1}^2 G_i)^{1/2} \), proving the result when \( g = 2 \) and \( \lambda(C_0) = 0 \).

When \( \lambda(C_0) \neq 0 \), we have to show (4.18) only on \( D_2^g \) (Lemma 5). All the above steps in the proof will go through for all \( (z_i, w_i; \ i = 1, 2) \) in \( D_2^g \). Hence if \( \lambda(C_0) \neq 0 \), we have our required LSD. This proves the Theorem when \( g = 2 \).

For general \( g > 2 \), note that we can write \( \{0, 1, 2, \ldots, n\} \) as \( \{b_1 k^g - 1 + b_2 k^{g-2} + \cdots + b_{g-1} k + b_g : 0 \leq b_i \leq k - 1, \ i = 1, 2, \ldots, g\} \). So we can write the sets \( \mathcal{A}_j \) explicitly using this decomposition of \( \{0, 1, 2, \ldots, n\} \) as done in \( n = k^2 - 1 \) case. For example if \( g = 3 \), \( \mathcal{A}_j = \{b_1 k^2 + b_2 k + b_3, b_2 k^2 + b_3 k + b_1, b_3 k^2 + b_1 k + b_2 \} \) for \( j = b_1 k^2 + b_2 k + b_3 \) (except for finitely many \( j \), bounded by \( v_{k,n} \) and they do not contribute to this limit). Using this fact and proceeding as before we will have the LSD as \( (\prod_{i=1}^g G_i)^{1/g} \) such that \( (\mathcal{R}(G_i), \mathcal{I}(G_i); \ i = 1, 2, \ldots, g) \) has distribution \( \mathcal{F}_g \).

\[ \square \]

5 Appendix

Proof of Lemma 7.

\[
\lambda_k = \frac{1}{\sqrt{n}} \sum_{t=0}^{n-1} x_t e^{i\omega_k t}
\]

\[
= \frac{1}{\sqrt{n}} \sum_{j=-\infty}^{\infty} a_j e^{i\omega_k j} \sum_{t=0}^{n-1} \epsilon_{t-j} e^{i\omega_k (t-j)}
\]

28
Note that if $|j| < n$, $U_{nj}$ is a sum of $2|j|$ independent random variables, whereas if $|j| \geq n$, $U_{nj}$ is a sum of $2n$ independent random variables. Thus $\mathbb{E}|U_{nj}|^2 \leq 2 \min(|j|, n)$. Therefore, for any fixed positive integer $l$ and $n > l$,

$$
\mathbb{E}|Y_n(\omega_k)|^2 \leq \frac{1}{n} \left( \sum_{j=-\infty}^{\infty} |a_j| (\mathbb{E}U_{nj}^2)^{1/2} \right)^2 \leq \frac{2}{n} \left( \sum_{j=-\infty}^{\infty} |a_j| |\min(|j|, n)|^{1/2} \right)^2 \leq 2 \left( \frac{1}{\sqrt{n}} \sum_{|j| \leq l} |a_j||j|^{1/2} + \sum_{|j| > l} |a_j| \right)^2.
$$

The right side of the above expression is independent of $k$ and as $n \to \infty$, it can be made smaller than any given positive constant by choosing $l$ large enough. Hence, $\max_{1 \leq k \leq n} \mathbb{E}|Y_n(\omega_k)|^2 \to 0$. □

**Proof of Lemma 8.**

$$
\frac{1}{\sqrt{n}} \sum_{t=1}^{m} x_t \cos \frac{2\pi kt}{n} = \frac{1}{\sqrt{n}} \sum_{t=1}^{m} \sum_{j=-\infty}^{\infty} a_j \epsilon_{t-j} \left[ \cos \frac{2\pi k(t-j)}{n} \cos \frac{2\pi kj}{n} - \sin \frac{2\pi k(t-j)}{n} \sin \frac{2\pi kj}{n} \right] = a_1(e^{i\omega_k}) \left[ \sum_{t=1}^{m} \epsilon_t \cos \frac{2\pi kt}{n} \right] - a_2(e^{i\omega_k}) \left[ \sum_{t=1}^{m} \epsilon_t \sin \frac{2\pi kt}{n} \right] + Y_{n,k},
$$

where

$$
Y_{n,k} = \frac{1}{\sqrt{n}} \sum_{j=-\infty}^{\infty} a_j \left[ \cos \frac{2\pi kj}{n} U_{k,j} - \sin \frac{2\pi kj}{n} V_{k,j} \right],
$$

$$
U_{k,j} = \sum_{t=1}^{m} \left[ \epsilon_{t-j} \cos \frac{2\pi k(t-j)}{n} - \epsilon_t \cos \frac{2\pi kt}{n} \right], \quad V_{k,j} = \sum_{t=1}^{m} \left[ \epsilon_{t-j} \sin \frac{2\pi k(t-j)}{n} - \epsilon_t \sin \frac{2\pi kt}{n} \right].
$$

Note that if $|j| < m$, $U_{k,j}, U'_{k,j}$ are sums of $2|j|$ independent random variables, whereas if $|j| \geq m$, $U_{k,j}, U'_{k,j}$ are sums of $2m$ independent random variables. Thus $\mathbb{E}|U_{k,j}|^2 \leq 2 \min(|j|, m)$. Therefore,
for any fixed positive integer \( l \) and \( m > l \),

\[
\mathbb{E}(Y_{n,k})^2 \leq \frac{2}{n} \mathbb{E} \left[ \left( \sum_{j=\infty}^{\infty} a_j \cos \frac{2\pi kj}{n} U_{k,j} \right)^2 + \left( \sum_{j=\infty}^{\infty} a_j \sin \frac{2\pi kj}{n} V_{k,j} \right)^2 \right] \\
\leq \frac{4}{n} \left[ \left( \sum_{j=\infty}^{\infty} |a_j| \mathbb{E}(U_{k,j}^2)^{1/2} \right)^2 + \left( \sum_{j=\infty}^{\infty} |a_j| \mathbb{E}(V_{k,j}^2)^{1/2} \right)^2 \right] \quad (\because \sum_{-\infty}^{\infty} |a_j| < \infty) \\
\leq \frac{8}{n} \left( \sum_{j=\infty}^{\infty} |a_j| \{\min(|j|, m)^{1/2} \right)^2 \\
\leq 8 \left( \frac{1}{\sqrt{n}} \sum_{|j| \leq l} |a_j| |j|^{1/2} + \sum_{|j| > l} |a_j| \right)^2.
\]

The right side of the above expression is independent of \( k \) and as \( n \to \infty \), it can be made smaller than any given positive constant by choosing \( l \) large enough. Hence, \( \max_{1 \leq k \leq m} \mathbb{E}(Y_{n,k})^2 \to 0. \) \( \Box \)
